## THE UNITED STATES PATENT AND TRADEMARK OFFICE

Applicant: John Christian Hermansen et al. Art Unit: 2641

Serial No.: 10/055,178 Examiner: Joon H. Hwang

Filed : January 25, 2002

Title : SYSTEM AND METHOD FOR ADAPTIVE MULTI-CULTURAL SEARCHING

AND MATCHING OF PERSONAL NAMES

## MAIL STOP AMENDMENT

Commissioner for Patents P.O. Box 1450 Alexandria, VA 22313-1450

## DECLARATION IN RESPONSE TO THE REQUIREMENT OF 37 CFR § 1.105

This declaration is prepared in response to the 37 C.F.R. § 1.105 requirement in the Office Action mailed on October 21, 2004.

I, the Declarant, am one of the named inventors on U.S. Patent Application No. 10/055,178, in which an office action was mailed on October 21, 2004. The Office Action includes a 105 requirement relating to (i) PC-NAS and (ii) products and services of Language Analysis Systems, Inc. ("LAS").

The present application, as-filed, included a paragraph asserting to describe PC-NAS, stating in part that "The assignee has developed a software program known as PC-NAS. An early version of this program was incorporated into a government computer system more than one year before the priority date of this application." Specification at page 5, lines 11-13. This statement is inaccurate for at least the reason that PC-NAS was not incorporated into a government computer system more than one year before the priority date of this application. Because the statement was inaccurate, I, through my patent attorneys, removed the PC-NAS paragraph from the specification in an amendment filed on April 12, 2004.

An investigation into LAS's products and services was performed that involved me, at least one other individual at LAS, and my patent attorneys. The purpose of the investigation was to determine which, if any, of LAS's products and services were prior art to the present application or should otherwise be disclosed to the U.S. Patent & Trademark Office ("PTO"). In the course of the investigation, we determined that PC-NAS had never been disclosed outside of LAS.

Applicant: John Christian Hermansen et al.

Serial No.: 10/055,178 Filed: January 25, 2002

Page : 2 of 3

During the investigation, however, we did determine that four products/services of LAS should be disclosed to the PTO. These four are: (i) Arabic Name Classifier, (ii) Arabic Name Analyzer, (iii) Consular Lookout And Support System, and (iv) Distributed Name Check. These four products/services are each described and disclosed in another Declaration by me that was filed in the present case on July 13, 2004, as part of an Information Disclosure Statement.

Attorney's Docket No.: 16441-012002

I am aware that the website www.archive.org (the "archive website") has a number of documents purporting to be archives of the LAS website on various dates. I do not know whether or not these documents are accurate. The archive website includes four documents, and only four, that are dated prior to March 25, 1998, which is the priority date of the present application. The dates of the four documents, according to the archive web site, are: 2/1/1997, 7/11/1997, 10/21/1997, and 2/6/1998. The Examiner notes in the 105 requirement that the 10/21/1997 document on the archive website describes a Suite of Tools including NameCheck, NameClassifier, NameRegularizer, Intelligent Search Data Generator, and PhoneticNameKey tools. The Examiner requests disclosure relating to these tools.

During the investigation I reviewed printouts of all four of the www.archive.org documents dated prior to March 25, 1998. During my review, I noticed that the oldest two documents did not contain material describing the Suite of Tools mentioned by the Examiner. That is, the Suite of Tools first appeared in the 10/21/1997 document, and does not appear in either the 2/1/1997 document or the 7/11/1997 document. Accordingly, the Suite of Tools is not in a document having a date one year prior to the priority date. Further, to the best of my knowledge, the Suite of Tools was not disclosed outside of LAS more than one year prior to March 25, 1998.

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patents issued thereon.

Commissioner for Patents P.O. Box 1450 Alexandria, VA 22313-1450

## DECLARATION OF JOHN CHRISTIAN HERMANSEN

This declaration relates to the following systems: Arabic Name Classifier ("ANC"), Arabic Name Analyzer ("ANA"), Consular Lookout And Support System ("CLASS"), and Distributed Name Check ("DNC").

## ANC

To the best of Declarant's recollection, ANC was written as a design document and delivered to a customer no later than the end of 1996.

ANC accepted a romanized input name and a COB associated with the input name, and produced a binary result indicating whether the input name was considered to be Arabic. Specifically, ANC determined a single surname for the input name, and compared that surname against a list of surnames that were known both to be from the COB and to be Arabic. If there was an exact spelling match, then ANC determined that the input name was Arabic and reported this determination to a user. If there was not an exact match, then ANC (i) performed a digram analysis on the input surname to determine the digrams present, (ii) produced an indicator of the similarity between the digram analysis and digram results for Arabic surnames from the COB, (iii) compared the value of the indicator to a threshold value representing confidence in the similarity and, based on this comparison, produced a binary result indicating whether the input name was considered to be Arabic, and (iv) reported the binary result to a user.

## ANA

To the best of Declarant's recollection, ANA was written as a design document and delivered to a customer no later than the end of 1996. ANA accepted a romanized input name

Attorney's Docket No.: 16441-012001

Applicant: John Christian Hermansen et al.

Serial No.: 09/275,766 Filed: March 25, 1999

Page

2 of 4

known to be Arabic, and applied various modification rules to a single surname of the input name. The rules were based on known spelling differences in Arabic surnames, and application of the rules produced a resulting surname which could be different from the surname of the input name. ANA then produced a key representing the resulting surname, and the key could be used to pull names from a database.

## CLASS

To the best of Declarant's recollection, no later than the end of 1991 (i) according to the terms of a contract with the United States government, and for compensation, Language Analysis Systems provided a design to the United States government in the United States of America proposing linguistics processing features for CLASS, (ii) according to the terms of a contract between another party (not Language Analysis Systems) and the United States government, and for compensation, CLASS was implemented in software by the other party, with the implementation generally following the proposed design from Language Analysis Systems, and CLASS was provided to the United States government in the United States of America, and (iii) CLASS was operated on a mainframe in the United States of America and accessed by terminals in one or more foreign countries.

CLASS accepted an input name and determined a rank-ordered list of name; from a database, where the names in the list were considered to be possible matches for the input name. More specifically, CLASS:

- (1) received the input name and various related or corresponding inputs including one or more "compressed name" ("CN") key(s) for corresponding sumame(s), a corresponding COB, a corresponding date of birth ("DOB"), and possibly a corresponding state of birth,
- (2) identified component elements of the input name (e.g., surname and given name), and identified a first initial of the given name,
- (3) identified digrams within each separate component element of the input name ("input name digrams"),
- (4) derived a set of names from within a database for comparison to the input name, the set of names being derived based on the input name, the one or more CN keys, the DOB, and the first initial of the given name,

Applicant: John Christian Hermansen et al.

Serial No.: 09/275,766 Filed

: March 25, 1999

Page

: 3 of 4

Augmey's Docket No.: 16441-012001

(5) identified digrams for the component elements of the names in the set of names ("database name digrams").

- (6) selected a set of weighting rules for producing a score indicating the extent to which two names matched each other, the set of weighting rules being selected based on the COB of the input name,
- (7) compared the input name with each name in the set of names, the comparison including comparing the input name digrams to the database name digrams,
- (8) generated a metric for each name in the set of names by applying the set of weighting rules during the comparison of the input name with each name in the set of names,
- (9) rank-ordered all names in the set of names having a metric greater than a threshold score, the threshold score indicating that the input name matches a particular name from the set of names, and
  - (10) provided the rank-ordered names to the user.

The set of weighting rules assigned various points to a particular name in the set of names based on a comparison of the particular name and the input name. For example, various points might be assigned depending on whether (i) corresponding element(s) in the particular name and the input name had similar digram results, (ii) the length of one or more elements was the same in the particular name and the input name, (iii) the DOBs of the particular name and the input name were within a predetermined timeframe of each other, (iv) the COB of the input name was the same as the COB associated with the particular name, (v) the elements of the particular name and the input name were in the same order, and (vi) the state of birth was the same for both the particular name and the input name.

## DNC

To the best of Declarant's recollection, no later than February 1997 (i) according to the terms of a contract with the United States government and for compensation, DNC was developed by Language Analysis Systems as a computer program and delivered by Language Analysis Systems to the United States government in the United States of America, and (ii) DNC was operated in one or more foreign countries. DNC was similar to CLASS, as described above. except that (i) DNC did not receive or use a key for the surname(s) of the input name, (ii) DNC

Attorney's Docket No. 16441-012001

Applicant: John Christian Hermansen et al.

Serial No.: 09/275,766 Filed: March 25, 1999

Page : 4 of 4

derived the set of names based on the DOB, the COB, and the state of birth (if available), and without reference to a key or the first initial of the given name, and (iii) DNC ran on a personal computer and not on a mainframe, so that when operated in a foreign country DNC only ran on a personal computer in the foreign country and not on a mainframe in the United States of America.

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patents issued thereon.

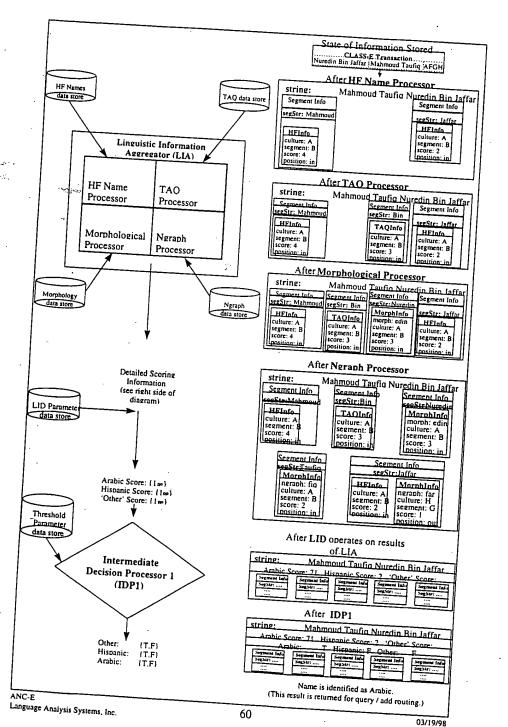

Respectfully submitted.

## SOFTWARE DESIGN DESCRIPTION AUTOMATIC NAME CLASSIFIER FOR CLASS-E (ANC-E)

#### INTRODUCTION

. 1.

rolel. Project Background

1.1.1. Legacy Consular Lookout And Support System (CLASS) and CLASS-E

The Consular Lookout and Support System (CLASS) performs namechecks of visa and passport applicants in support of the issuance process. Used by United States passport agencies, consulates, and border inspection agencies, CLASS serves as an automated index to manual files. CLASS is a centralized system residing on mainframe computers at the Department of State in Washington, DC. The Bureau of Consular Affairs, Consular Systems Division (CA/EX/CSD) of the Department of State (DOS) has responsibility for development, maintenance, and operation of CLASS.

CLASS was implemented in 1989; since that time, major advancements have occurred in database management systems, large-scale computers and their operating systems, and data telecommunications. In addition, namematching techniques have also evolved based on the DOS's experience with the system and further linguistic research. This has led DOS in determining the necessity for a newer, more modernized system, CLASS-E (Consular Lookout and Support System-Enhanced).

The CLASS-E modernized version of automated name-matching will incorporate state-of-the-art hardware, data telecommunications, and database management technology to migrate the CLASS application from its Virtual Storage Access Method (VSAM) environment into a DB2 relational database system. In addition to providing virtually uninterrupted access to the lookout databases 24 hours a day, 7 days a week to the VO, PPT, overseas posts and support users, this enhanced system will position CLASS-E to incorporate advanced culturally-sensitive namecheck methods.

1.1.2. Culturally Sensitive Name Searching in CLASS-E
Personal naming systems vary widely from culture to culture. That is,
names from around the world do not necessarily fit cleanly into the

Anglophone name model. Several of the manifestations of these differences are

- · Anglicization of Non-English sound patterns (Mladevic written as Miladevich)
- · Variant romanization schemes (Arabic Waseem ~ Ouassime, Shareef ~ Cherife; Chinese Xia ~ Hsia ~ Sya
- Dialectal variants (Arabic Abu Bakir [Egyptian] ~ Boubker [Moroccan]; Chinese Wu [Mandarin] ~ Ng [Cantonese, Fukien])
- · Variant roman spelling conventions (French silent letters, German sch for English sh)

When dealing with Arabic and Chinese names and those of other languages that do not use the Roman alphabet, foe example, one quickly discovers one major source of name variation lies in how names are transliterated into roman characters from the original scripts. For both Arabic and Chinese, there are numerous competing transliteration standards, as well as less formal traditions. Xia, Hsia, and Sya, for example, are all romanized variants of the same Chinese name. Kassim, Qasim, Casem, Kacem and Asim are romanized variants of the same Arabic name. In Arabic, name variation often goes beyond the phonetic level. Analyzable elements such as "Abu" show up in many different forms, depending on dialect (e.g., Abu Bakir ~ Boubker). In Chinese, multiple traditions of transliteration are one of the sources of name variation; dialect issues also abound (e.g., Wu ~ Ng). Hispanic names, which make up the largest portion of the data base, place information value on name parts in a manner that is not consistent with Anglophone naming conventions. Exploitation of this culturally-specific information in the name search process leads to improved precision, recall, and overall system performance.

## 1.1.3. Automatic Name Classifier-E (ANC-E) in CLASS-E

The need for automatic name classification has become a become an undisputed necessary first step in the process of applying linguistic knowledge to solve the problems associated with name searching in large multicultural databases. In this environment, name classification serves as a means of routing queries to the proper language- and culture-specific algorithms. Currently, Legacy CLASS supports a single module, called ANI, which begins to address this need by returning a Boolean value indicating whether a name is or is not Arabic. If a name qualifies as Arab, it is subject to processing by an initial implementation of the Arabic algorithm designed by LAS for the State Department. Currently the expanding needs of the State Department are being addressed in the development a second culture-specific algorithm which will handle Hispanic names. The addition of a Hispanic algorithm to CLASS's

functionality requires the addition of a method for identifying Hispanic names in a manner similar that of ANI.

At this juncture, it is reasonable to turn enhancement efforts towards the development of a single, integrated, expandable algorithm for name classification which will address the need for classifying Arabic and Hispanic names, and which will anticipate the imminent addition of other languages. The integrated automatic name classification algorithm will represent a significant improvement over the existing ANI algorithm in that it will incorporate more linguistic knowledge, it will allow for future expansion with minimal coding effort, and it will allow information about a record's country of birth (COB) to contribute to the query routing decision. Figure 1-1 displays the integration of ANC-E within the CLASS-E system.

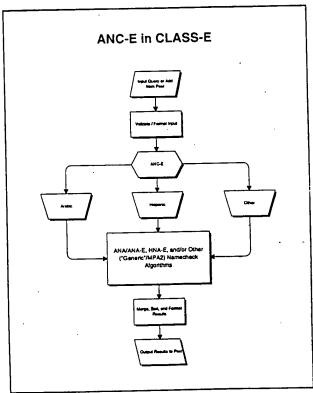

Figure 1-1

#### 1.2. Scope

This document describes the linguistic motivation, requirements, and high level design for an Automatic Name Classifier (ANC) which will automatically determine whether a name qualifies as Hispanic or Arabic. The document's purpose is to provide information about the proposed design in order to facilitate the analysis and planning necessary to prepare for eventual implementation.

Intended to serve as the module that will provide for the integration of the enhanced Arabic Name Search Algorithm for CLASS-E (ANA-E) and the Hispanic Name Search Algorithm (HNA-E) into the overall CLASS-E architecture, the Automatic Name Classifier for CLASS-E (ANC-E) will provide the capability to automatically determine whether an input name is Arabic, Hispanic, or neither. In this system, names may be qualified as Arabic or Hispanic by virtue of passing one of two thresholds, or, conversely, may be disqualified as Arabic or Hispanic by virtue of having many characteristics of 'Other' types of names. The ANC-E system has been designed with an open architecture intended to facilitate the inclusion of additional cultures in the event that CLASS-E adds other culture-specific search algorithms in the future. Furthermore, since the ANC-E is data-driven, it is possible to tune its level of sensitivity for each individual culture being identified.

In CLASS-E the concept of the Legacy CLASS Multi-Pipe Architecture will be carried forward to include a distinct Arabic processing algorithm and a distinct Hispanic processing algorithm as well as perhaps others in the future. The type of processing to which an input name will be submitted will be a business decision of CA/EX/CSD and may to some degree be dependent on the impact that multiple processing of an input name would have on the performance of the system. It is likely that input names that are classified by the Advanced Name Classifier for CLASS-E (ANC-E) will be submitted to multiple of the following processors: the generic CLASS-E generic processing algorithm, the DOB processing algorithm, the ANA-E algorithm, and the HNA-E algorithm. The ANC-E will provide a determination as to which culture or cultures a name belongs; what use is made of this determination is a business decision of CA/EX/CSD. This decision will affect the design of the interface between the ANC-E and the rest of the CLASS-E system.

## 1.3. Definitions and Acronyms

## 1.3.1. Definitions

Affix\*

A name particle which is neither a title nor a qualifier. Affixes in the ANC-E are defined as being delineated by white space; for example,

ANC-E Language Analysis Systems, Inc.

'de' in 'Tirso de Molina'. Note that, contrary to normal usage within linguistics, affixes are in contrast to (bound) morphemes, which are

not delineated by white space.

Digraph Field

A two character n-gram.

A data entry mechanism which allows the user to input a fixed number of characters. The fields typically referred to in the CLASS environment are the Given Name Field and the Surname Field.

environment are the Given Name Field and the Surname Field

Given Name

Note that it is important to distinguish between given name and surname data entry Fields and given name and surname data elements, since data elements do not always occur in the proper field.

The portion of a name which uniquely identifies an individual member of a family, as opposed to surname. Given Names may include one or more segments; for example, 'Mary Jane' in 'Mary

Jane Cassoway'.

Infix

" Dies

ء المفتد

41.77

A substring occurring the middle of a name segment, but not at the

edges. Both n-grams and morphemes may be infixes.

Morpheme

(here, bound morpheme) A meaningful, variable length substring of a name segment. Morphemes may occur as prefixes, infixes or suffixes.

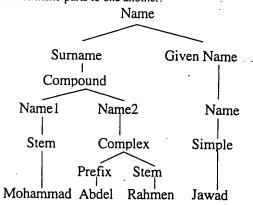

Examples: '-ovitch' in 'Berkovitch'. Note that morphemes contrast

with affixes.

Morphology Name

Referring to morphemes.

The general term referring to the entire collection of segments which refer to a single person. A name may include one or more given names, one or more surnames and zero or more particles. For the purposes of ANC-E, a Name is considered to consist only of alphabetic characters and white space. The diagram below illustrates the relation of name parts to one another:

N-Gram

A variable length sequence of characters which serves as a useful

<sup>\*</sup> Note that these terms have a slightly modified or restricted definition within the context of ANC-E.

indicator of linguistic affinity, but which is not associated with a meaning. N-Grams may be considered to be indicators of the sound or spelling patterns of a language; for example, -ez is a Hispanic N-

Gram.

Particle

141.14

A functional name element delineated by white space. Titles, affixes and qualifiers are the three kinds of particles identified in the ANC-E

algorithm.

Prefix A substring (N-Gram or morpheme) or a particle (affix) occurring at

the beginning of a name segment.

Qualifier A meaningful particle which represents a kinship relation or earned

social status; for example, Jr. or Ph.D. Qualifiers typically occur at

the end of a name field.

Segment Any element within a name which is delineated by white space.

Suffix A substring (N-Gram or morpheme) or a particle (affix) occurring at

the end of a name segment.

Surname The portion of a *name* which may indicate family membership, as opposed to *given name*. Surnames may include one or more segments

and zero or more particles; for example, 'Fernandez de la Puente' in

'Hector Fernandez de la Puente'.

Syntax The rules governing the order of name elements.

Title A meaningful particle which represents a term of address and which

typically occurs at the beginning of a name field. Examples: Dr. or

Sir. Titles may be indicative of social position.

Trigraph A three character n-gram.

Variant An alternate spelling of a name segment; for example, Mohammad

6

and Muhamed are variants of one another. Variants may be predictable, as in this example, or unpredictable, as evidenced by

typographical or other data entry errors.

- 2.2. CLASS-E Functional Requirements Specification (FRS)
  - 2.2.1. Note: the CLASS-E FRS has not yet been finalized.

#### Decomposition Description 3.

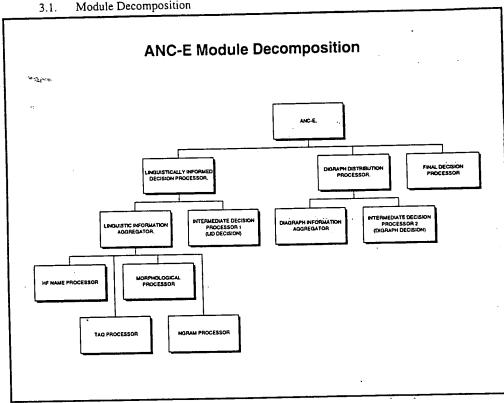

Figure 3-1

- 3.1.1. Automatic Name Classifier for CLASS-E (ANC-E) Module Decomposition
  - 3.1.1.1. Identification

This program is referred to as the Automatic Name Classifier for CLASS-E (ANC-E).

3.1.1.2. Type

ANC-E is a program that is part of the larger CLASS-E system. It can be viewed as a "shell" program in that it is to

serve as a layer surrounding all of the culturally-specific name search algorithms implemented in CLASS-E.

## 3.1.1.3. Purpose

- 3.1.1.3.1. The need for automatic name classification is a necessary first step in the process of applying linguistic knowledge to solve the problems associated with name searching in large multicultural databases.
- 3.1.1.3.2. In the CLASS-E environment, name classification serves as a means of routing queries to the proper language- and culture-specific algorithms.
- 3.1.1.3.3. In addition to the rudimentary identification of Arabic names currently implemented in ANI, the addition of a Hispanic name search algorithm to CLASS-E's functionality requires the addition of a method for identifying Hispanic names.
- 3.1.1.3.4: ANC-E is a single, integrated algorithm for name classification which will address the need for classifying Arabic and Hispanic names, and which will anticipate the possible addition of other languages.
- 3.1.1.3.5. This integrated automatic name classification algorithm will represent a significant improvement over the existing ANI algorithm in that it will incorporate more linguistic knowledge, and will allow information about a record's country of birth (COB) to contribute to the query routing decision.

## 3.1.1.4. Function

- 3.1.1.4.1. The ANC-E will take as input a surname, given name, and COB in standard CLASS-E format.
  - 3.1.1.4.1.1. There are two options with respect to the methodology for handling an input name and gathering the aggregate data

that will lead to the determination of cultural affinity for that name.

## 3.1.1.4.1.1.1. If ANC-E is to be implemented in an objectoriented environment, an object can be created which will contain all of the accumulated information to be used in the determination of cultural affinity. This object travels through the ANC-E system, thus allowing access to the accumulated information at any time. If ANC-E is integrated with the culturally-sensitive name search algorithms in CLASS-E, this option has the advantage that the all of the attendant linguistic information produced by ANC-E processing could be passed, along with the name, to the culturally-sensitive namecheck algorithm for further processing. That is, certain common linguistic processing would need to be performed only one time for the entire namecheck process, rather than once for each specific name search

3.1.1.4.1.1.2. If ANC-E is to be implemented in a non-object-oriented environment, ANC-E will process the name and COB as separate string values, and will output a either a single cultural affinity indicator (e.g. Arabic, Hispanic, or Other) or three Boolean values, one for each

algorithm invoked.

culture under consideration, depending on the business decision made by CA/EX/CSD. If this option is chosen, linguistic processing information and scoring internal to ANC-E will not be available to outside processes.

- 3.1.1.4.2. The ANC-E will provide a determination as to which culture or cultures a name belongs.
- 3.1.1.4.3. The use that is made of the cultural affinity determinations made by ANC-E is a business decision of CA/EX/CSD (i.e. whether to allow a name to be processed by more than one namecheck algorithm, and whether ANC-E shall return more than one possible cultural affinity for a given input name). This decision will affect the design of the interface between the ANC-E and the rest of the CLASS-E system.

#### 3.1.1.5. Subordinates

The following processes are subordinate to the main ANC-E program:

- The Linguistically Informed Decision Processor (LID)
- The Digraph Distribution Processor
- The Final Decision Processor.
- 3.1.2. Linguistically Informed Decision (LID) Module Decomposition

#### 3.1.2.1. Identification

This module is referred to as the Linguistically Informed Decision Processor (LID).

#### 3.1.2.2. Type

The LID is a module which contains two subordinate modules. The first subordinate module performs linguistic analysis, gathering linguistic information and scoring for the input name. The second subordinate module makes decisions as to the cultural affinity of the name, based on the scoring information gathered by the first module.

## 3.1.2.3. Purpose

- 3.1.2.3.1. The LID exists to provide a linguistically well-founded decision as to the cultural affinity of the input name.
- 3.1.2.3.2. As the first phase of processing, the LID addresses performance requirements by basing this decision on multiple readily observable linguistic factors, thus obviating the need for processing by the more intensive statistical digraph model and for reliance on name-external factors, such as Country of Birth (COB).
- 3.1.2.3.3. Furthermore, the LID provides a more linguistically-rich context in which to determine the cultural affinity of the input name than does it's purely digraph-distribution-based predecessor, ANI. Thus ANC-E is better able to identify names that are Hispanic or Arabic and to eliminate those that are not. Linguistic Indicators provide a rich source of information about the cultural affinity of a name. The LID processor will serve as a means of assuring that names which are strongly Arabic or Hispanic are qualified and, conversely, that names which have strong characteristics of some other culture are disqualified. Names which qualify as Hispanic, Arabic or 'Other' will not be submitted to the Digraph Analysis function.

## 3.1.2.4. Function

- 3.1.2.4.1. All linguistic indicator processing will take place before digraph analysis and will constitute a linguistically informed decision (LID) mechanism.
- 3.1.2.4.2. The LID accumulates and weighs factors from multiple knowledge sources in order to determine whether there is a sufficient amount of evidence to identify the input name as being Hispanic or Arabic, or, conversely, if there is enough

evidence to discount the possibility that the input name is either Hispanic or Arabic.

- 3.1.2.4.3. The LID will assign points to a name based on a weighted tabulation of scores from the following data sources:
  - High Frequency name data
  - TAQ data
  - · Morphological data
  - Ngram data
- 3.1.2.4.4. The function of the LID is to determine a score for each cultural affinity being classified, and a score for 'Other'. For each culture, a name must get a score which passes its corresponding LID Threshold in order to be labeled as Arabic, Hispanic or "Other".
- 3.1.2.4.5. Each of the four types of linguistic indicator (listed in 3.1.2.4.3) will be associated with a set of four parameters, indicating the weight that a LID element is to be given.
- 3.1.2.4.6. The score for each language group will be calculated as a summation of the combination of the applicable factor times the score for each indicator found in the name string. Scoring details are included in the decomposition descriptions of the respective modules. (See sections 3.1.3 3.1.8.)
- 3.1.2.4.7. After all of the agents have processed the input name, the LID combines the detailed scoring information returned by the LIA to produce a LID score for Hispanic, Arabic, and for Other.
- 3.1.2.4.8. The LID passes the LID score to the Intermediate Decision Processor 1 for comparison to LID thresholds for cultures under consideration.
- 3.1.2.4.9. There are two alternatives for the output of the processing of the input name performed by the LID: an object containing linguistic processing information and scores or three Boolean values indicating whether the name has passed the LID

10.7

thresholds for Arabic, Hispanic, or Other. For more information, see 3.1.1.4.1.1.

- 3.1.2.4.10. If the LID identifies a name as Hispanic, Arabic, or Other (or any combination thereof), no further processing is required.
- 3.1.2.4.11. For a detailed example of LID processing, see the figures in Appendix A.

## 3.1.2.5. Subordinates

artič.

The following processes are subordinate to the LID:

- The Linguistic Information Aggregator (LIA)
- Intermediate Decision Processor 1 (LID Decision).
- 3.1.3. Linguistic Information Aggregator (LIA) Module Decomposition
  - 3.1.3.1. Identification

This module is referred to as the Linguistic Information Aggregator (LIA).

3.1.3.2. Type

LIA is a module which contains four subordinate functions (agents) all of which contribute to the final decision or decisions made by the LID as to the cultural affinity of the input name. Thus, conceptually, LIA and the LID can be viewed as parts of a blackboard (voting) system, an expert system, or as parts of a system with multiple intelligent agents.

#### 3.1.3.3. Purpose

- 3.1.3.3.1. The LIA exists to enable the linguistic decision made by the LID. The LIA controls the flow of information from the four linguistic agents subordinate to it.
- 3.1.3.3.2. If the implementation choices accompanying the object-oriented description of ANC-E are chosen (see 3.1.1.4.1.1.1), LIA could help performance by allowing certain linguistic processing to occur only once for each name check, rather than once for each algorithm invoked. (Note: In Legacy CLASS each algorithm is referred to as a separate 'pipe'.)

#### 3.1.3.4. Function

- 3.1.3.4.1. LIA accumulates linguistic information factors from multiple knowledge sources for each culture under consideration (i.e. currently Hispanic, Arabic, and Other).
- 3.1.3.4.2. In cases of conflict, the order of precedence for identifying items within an input name is TAQ particle, Morpheme, Ngram.
  - 3.1.3.4.2.1. If a string of letters is identified as a TAQ particle for a particular culture, a substring of that same string (including the entire string itself) cannot also be identified as a Morpheme or an Ngram for that same culture.
  - 3.1.3.4.2.2. If a string is identified as a Morpheme for a particular culture, the characters that make up that Morpheme cannot also be considered as part of an Ngram for that culture.
  - 3.1.3.4.2.3. HF Names from a given culture can contain Morphemes and / or Ngrams for that same culture; however, the precedence rules in sections 3.1.3.4.2.1 and 3.1.3.4.2.2 apply.
- 3.1.3.4.3. As the subordinate functions (agents) process the input name, detailed scoring information is collected by LIA, and weighted according to its information value as indicated in the LID Parameter data store.
- 3.1.3.4.4. After all of the agents have provided their input, the LIA returns this detailed scoring information to the LID.
- 3.1.3.4.5. For a detailed example of aggregation of information by LIA, see the figures in Appendix A.

## 3.1.3.5. Subordinates

The following processes are subordinate to the LIA:

- The High Frequency (HF) Name Processor
- The Title, Affix, Qualifier (TAQ) Processor
- The Morphological Processor
- The Ngram Processor.

## 3.1.4. High Frequency (HF) Name Processor Module Decomposition

## 3.1.4.1. Identification

This function is referred to as HF Name Processor.

#### 3.1.4.2. Type

The HF Name Processor is a function which is invoked by the Linguistic Information Aggregator (LIA).

#### 3.1.4.3. Purpose

Certain given names and surnames occur much more frequently in some cultures than in others. The name "Mohammed", for example occurs frequently in Arabic names. The surname "Rodriguez" lends support to the possibility that the name in question is Hispanic. The name "Nganga" in any position suggests that the name might not be either Arabic or Hispanic. The HF Name Processor exists to take advantage of the information available in high frequency names in the cultural identification of the name.

## 3.1.4.4. Function

- 3.1.4.4.1. For each name segment present in the input name, the HF Name Processor determines whether that name is present in the HF Name data store.
- 3.1.4.4.2. If the name is present in the HF name data store, the HF Name Processor retrieves and records the culture, name field (given name or surname), and score associated with that name from the data store.
- 3.1.4.4.3. Also recorded for each HF name found is whether it was found in position or out of position. For example, since "Rodriguez" is listed as a surname in the HF Names data store, if it is found in the GN field in the input name, it

is reported as a surname considered to be out of position.

3.1.4.4.4. The HF Name Processor tracks scoring information for each HF name found, and returns this detailed scoring information to LIA.

3.1.4.5. Subordinates None.

----

- 3.1.5. Title, Affix, Qualifier (TAQ) Processor Module Decomposition
  - 3.1.5.1. Identification

    This function is referred to as the TAQ Processor.
  - 3.1.5.2. Type

    The TAQ Processor is a function which is invoked by the Linguistic Information Aggregator (LIA).
  - 3.1.5.3. Purpose

As noted in section 1.3.1, name fields have a syntactic structure which may be simple, compound, complex, or compound-complex. Name fields which are complex or compound-complex contain particles: titles, affixes, or qualifiers. These particles can be used to further narrow the range of possibilities for the cultural affinity of the input name. The TAQ Processor exists to make use of the information available in particles.

- 3.1.5.4. Function
  - 3.1.5.4.1. For each segment present in the input name, the TAQ Processor determines whether that segment is a particle present in the TAQ data store.
  - 3.1.5.4.2. If the segment is present in the TAQ data store, the TAQ Processor retrieves and records the culture, name field (given name or surname), and score associated with that TAQ particle from the data store.

- 3.1.5.4.3. Also recorded for each TAQ particle found is whether it was found in position or out of position. (See example in section 3.1.4.4.3.)
- 3.1.5.4.4. The TAQ Processor tracks scoring information for each HF TAQ particle found, and returns this detailed scoring information to LIA.
- 3.1.5.5. Subordinates None.
- 3.1.6. Morphological Processor Module Decomposition
  - 3.1.6.1. Identification

    This function is referred to as Morphological Processor.
  - 3.1.6.2. Type

    The Morphological Processor is a function which is invoked by the Linguistic Information Aggregator (LIA).
  - 3.1.6.3. Purpose

As noted and defined in section 1.3.1, morphological elements, such as -ovich, can play a large part in determining the cultural affinity of an input name. The Morphological Processor exists to take advantage of this information in the name classification process.

- 3.1.6.4. Function
  - 3.1.6.4.1. For each Morpheme present in the Morphology data store, the Morphological Processor determines whether that Morpheme is present in the input name.
    - 3.1.6.4.1.1. Note that the above processing differs from that in the HF Name Processor (3.1.4.4) and the TAQ Processor (3.1.5.4). Since the Morphology data store contains only bound Morphemes, that is Morphemes not surrounded by white space, it is not possible to locate them based on name segments, which are surrounded by white space.

      Rather, it is necessary to determine if any of the items listed in the

Morphology data store is a substring of any of the name segments present in the input name, within certain constraints. For more detailed information on identifying Morphemes in the input name, see sections 3.2.4 (Morphological Data Store Data Decomposition) and 3.1.6 (Morphological Processor Module Decomposition).

- 3.1.6.4.2. For each Morpheme found in the input name, the Morphological Processor retrieves and records the morpheme found, the culture, name field (given name or surname), and score associated with that Morpheme from the data store.
- 3.1.6.4.3. Also recorded for each Morpheme found is whether it was found in position or out of position. (See example in section 3.1.4.4.3.)
- 3.1.6.4.4. The Morphological Processor tracks scoring information for each Morpheme found, and returns this detailed scoring information to LIA.
- 3.1.6.5. Subordinates None.

3.1.7.3. Purpose

- 3.1.7. Ngram Processor Module Decomposition
  - 3.1.7.1. Identification

    This function is referred to as the Ngram Processor.
  - 3.1.7.2. Type
    - The Ngram Processor is a function which is invoked by the Linguistic Information Aggregator (LIA).
    - As described in section 1.3.1, Ngrams are strings of letters that occur with statistical significance in names with a given cultural affinity. The Ngram Processor exists to take advantage of this statistical phenomenon in the name typing process.

ا جاھائ ،

## 3.1.7.4. Function

- 3.1.7.4.1. For each Ngram present in the Ngram data store, the Ngram Processor determines whether that Ngram is present in the input name.
  - 3.1.7.4.1.1. Note that the above processing is similar to that in the Morphological Processor. (See section 3.1.6.4, and especially section 3.1.6.4.1.1 for a detailed note.)
- 3.1.7.4.2. For each Ngram found in the input name, the Ngram Processor retrieves and records the Ngram found, the culture, name field (given name or surname), and score associated with that Ngram from the data store.
- 3.1.7.4.3. Also recorded for each Ngram found is whether it was found in position or out of position. (See example in section 3.1.4.4.3.)
- 3.1.7.4.4. The Ngram Processor tracks scoring information for each Ngram found, and returns this detailed scoring information to LIA.
- 3.1.7.5. Subordinates None.
- 3.1.8. Intermediate Decision Processor 1 (LID Decision) Module Decomposition
  - 3.1.8.1. Identification

    This module is referred to as Intermediate Decision Processor 1 (IDP1).
  - 3.1.8.2. Type IDP1 is a function which is invoked directly by the Linguistically Informed Decision Processor (LID).
  - 3.1.8.3. Purpose

    IDP1 is the decision-making function of the LID. It determines whether enough linguistic information has been gathered from the various intelligent agents by LIA to

confidently determine that the input name belongs to one of the cultures being identified (currently Arabic, Hispanic, and Other).

## 3.1.8.4. Function

- 3.1.8.4.1. IDP1 accepts as input one aggregate LID score for each culture being identified as well as an aggregate LID score for Other.
- 3.1.8.4.2. For each LID score, IDP1 compares that score to the LID threshold for the appropriate culture (or Other).
- 3.1.8.4.3. If the LID score is greater than or equal to the appropriate LID threshold, IDP1 returns a value of True for the culture in question. If the LID score is less than the LID threshold for the culture in question, IDP1 returns a value of False for the culture in question.
  - 3.1.8.4.3.1. A True value indicates to the LID that enough evidence has been accumulated by LIA to confidently identify the name as belonging to the culture in question.
  - 3.1.8.4.3.2. A False value indicates to the LID that not enough evidence has been accumulated by LIA to confidently identify the name as belonging to the culture in question.
  - 3.1.8.4.3.3. A value of True can be returned for more than one cultural affinity.
  - 3.1.8.4.3.4. A value of False may be returned for all cultural affinities.
- 3.1.8.4.4. Alternatively, IDP1 could return a value for each culture equal to the LID score minus the LID threshold for that culture.
  - 3.1.8.4.4.1. Given the alternative above, the LID would interpret negative scores as

False values and nonnegative scores as True values.

- 3.1.8.4.4.2. The utility of this alternative is that if an object-oriented implementation is chosen, the values calculated by IDP1 could be incorporated into the object mentioned in section 3.1.1.4.1.1.1, and would be available as part of the information that the name object "knows" about itself for use in later processing.
- 3.1.8.4.5. If a return value of True for any culture (or for "Other") is obtained from IDP1, no further processing is required.
- 3.1.8.5. Subordinates None.
- 3.1.9. Digraph Distribution Processor Module Decomposition
  - 3.1.9.1. Identification

This module is referred to as the Digraph Distribution Processor.

3.1.9.2. Type

The Digraph Distribution Processor is a module which has two subordinate functions.

3.1.9.3. Purpose

The Arabic Name Identification (ANI) subprogram currently in use in Legacy CLASS is based purely on a model of digraph distribution in Arabic names. Digraph distribution information has proved useful in determining the cultural affinity of names. Based on a statistical model generated from digraph distribution statistics and initial and final trigraph statistics, the Digraph Distribution Processor lends additional information to the attempt to identify the provenance of the input name.

- 3.1.9.4. Function
  - 3.1.9.4.1. The Digraph Distribution Processor takes as input the surname from the name input to

- ANC-E. This portion of ANC-E operates only on surname data.
- 3.1.9.4.2. The Digraph Distribution Processor is invoked only when the LID has not been successful in assigning any cultural affinity to the input name. (See sections 3.1.2.4.10 and 3.1.8.4.5.)
- 3.1.9.4.3. The Digraph Distribution Processor calculates scores based on digraph distribution statistics for each culture in order to determine whether there is a sufficient amount of evidence to identify the input name as being Hispanic or Arabic. Note that there is no Digraph Distribution Score computed for Other.
- 3.1.9.4.4. The Digraph Distribution Parameters data store contains a Digraph Skew Factor for each cultural affinity.
- 3.1.9.4.5. The Total Digraph Distribution Score for the input name is equal to the Raw Digraph Distribution Score returned by the DIA plus the value of the Digraph Skew Factor for the appropriate culture.
- 3.1.9.4.6. The Digraph Distribution Processor passes the Total Digraph Distribution score for each culture to the Intermediate Decision Processor 2 for comparison to Digraph thresholds for cultures under consideration.
- 3.1.9.4.7. There are two alternatives for the output of the processing of the input name performed by the Digraph Distribution Processor: an object containing a Digraph Distribution Score for each culture, or two Boolean values indicating whether the name has passed the Digraph thresholds for Arabic or Hispanic. For more information, see 3.1.1.4.1.1.
- 3.1.9.4.8. If the Digraph Distribution Processor identifies a name as Hispanic, Arabic, or both no further processing is required.

## 3.1.9.5. Subordinates

The following processes are subordinate to the Digraph Distribution Processor:

- The Digraph Information Aggregator (DIA)
- Intermediate Decision Processor 2 (Digraph Decision).

## 3.1.10. Digraph Information Aggregator (DIA) Module Decomposition

## 3.1.10.1. Identification

This module is referred to as the Digraph Information Aggregator (DIA).

## 3.1.10.2. Type

The DIA is a process invoked by the Digraph Distribution Processor. The DIA operates only on surname segments consisting solely of alphabetic characters.

#### 3.1.10.3. Purpose

The DIA gathers the information necessary for the Digraph Distribution Processor to determine whether there is sufficient information to identify the input name as Hispanic or Arabic.

#### 3.1.10.4. Function

- 3.1.10.4.1. For purposes of DIA processing, a surname segment is defined as any string of characters delimited by white space.
  - 3.1.10.4.1.1. Given a surname containing more than one part as input, the name is segmented (based on white space).

    Each part of multi-part surnames is processed separately, and the scores are combined in the manner described below.
- 3.1.10.4.2. DIA will calculate a score for each surname segment by totaling the scores for all digraphs within the surname segment.
  - 3.1.10.4.2.1. The set of digraphs for a surname consists of all possible substrings of

two contiguous characters in the surname.

- 3.1.10.4.2.2. Word-boundaries are considered characters, so the additional digraphs "word-boundary+first-letter" and "last-letter+word-boundary" are included in the set of digraphs for each name.
- 3.1.10.4.2.3. In general, a surname segment of length n contains (n+1) digraphs, ordered from leftmost to rightmost.
- 3.1.10.4.3. Each digraph in the surname segment is looked up in a table containing scores for all possible digraphs for all cultural affinities being scored. DIA maintains a cumulative total of all digraph scores assigned to a surname segment.
- 3.1.10.4.4. Likewise, scores are assigned for the initial and final trigraphs of each name segment.
- 3.1.10.4.5. The initial and final trigraph scores are added to the cumulative score for that segment. A score is thus calculated for each segment of the surname.
- 3.1.10.4.6. The Raw Digraph Distribution Score for the input name is equal to the sum of all individual surname segment scores thus calculated.
- 3.1.10.5. Subordinates
- 3.1.11. Intermediate Decision Processor 2 (Digraph Decision) Module Decomposition
  - 3.1.11.1. Identification

This module is referred to as Intermediate Decision Processor 2 (IDP2).

3.1.11.2. Type

IDP2 is a function'which is invoked directly by the Digraph Distribution Processor.

ANC-E Language Analysis Systems, Inc.

## 3.1.11.3. Purpose

IDP2 is the decision-making function of the Digraph Distribution Processor. It determines whether enough digraph distribution information is present to confidently determine that the input name belongs to one of the cultures being identified (currently Arabic or Hispanic).

#### 3.1.11.4. Function

- 3.1.11.4.1. IDP2 accepts as input one Digraph Distribution Score for each culture being identified.
- 3.1.11.4.2. For each Digraph Distribution Score, IDP2 compares that score to the Digraph threshold for the appropriate culture.
- 3.1.11.4.3. If the Digraph Distribution Score is greater than or equal to the appropriate Digraph threshold, IDP2 returns a value of True for the culture in question. If the Digraph Distribution Score is less than the Digraph threshold for the culture in question, IDP2 returns a value of False for the culture in question.
  - 3.1.11.4.3.1.A True value indicates to the Digraph
    Distribution Processor that digraph
    distribution information is conclusive
    enough to confidently identify the name
    as belonging to the culture in question.
  - 3.1.11.4.3.2.A False value indicates to the Digraph Distribution Processor that digraph distribution information is not conclusive enough to confidently identify the name as belonging to the culture in question.
  - 3.1.11.4.3.3.A value of True can be returned for more than one cultural affinity.
  - 3.1.11.4.3.4.A value of False may be returned for all cultural affinities.
- 3.1.11,4.4. Alternatively, IDP2 could return a value for each culture equal to the Digraph Distribution

Score minus the Digraph threshold for that culture.

- 3.1.11.4.4.1. Given the alternative above, the
  Digraph Distribution Processor would
  interpret negative scores as False
  values and nonnegative scores as True
  values.
- 3.1.11.4.4.2. The utility of this alternative is that if an object-oriented implementation is chosen, the values calculated by IDP2 could be incorporated into the object mentioned in section 3.1.1.4.1.1.1, and would be available as part of the information that the name object "knows" about itself for use in later processing.
- 3.1.11.5. Subordinates None.
- 3.1.12. Final Decision Processor Module Decomposition
  - 3.1.12.1. Identification

This module is referred to as the Final Decision Processor.

3.1.12.2. Type

The Final Decision Processor is a module invoked directly by the ANC-E main program.

- 3.1.12.3. Purpose
  - 3.1.12.3.1. Although the LID and the Digraph Distribution Processor are each powerful methods for identifying the cultural affinity of names in themselves, some benefit can be gained from combining the judgments of these two modules when neither has been successful in reaching a conclusion within a reasonable level of certainty on its own.
  - 3.1.12.3.2. Additionally, within the CLASS-E system, information about the Country of Birth (COB)

will usually be available. Although this information is not generally sufficient to determine the cultural affinity of a name in itself, it could provide the additional evidence necessary to reach a conclusion when combined with the judgments of the LID and the Digraph Distribution Processor.

3.1.12.3.3. The final decision processor exists to take all of this information into account, in an effort to determine the cultural affinity of the input name by combining all available data when the individual data elements themselves are not strong enough indicators.

#### 3.1.12.4. Function

- 3.1.12.4.1. In the event that neither the LID nor the Digraph Distribution Processor is successful in determining a cultural affinity for the input name, the processing continues to the Final Decision Processor. (See sections 3.1.2.4.10, 3.1.8.4.5, and 3.1.9.4.8.)
- 3.1.12.4.2. If the options suggested in sections
  3.1.1.4.1.1.1, 3.1.8.4.4, and 3.1.11.4.4 are incorporated into the implementation, the final Decision Processor will have access to all of the information it needs to perform its task encapsulated in the name information object.

  Otherwise, the Final Decision Processor will take as input LID scores (for each cultural affinity and for Other) and digraph scores (for each cultural affinity) for the input name.
- 3.1.12.4.3. For each culture still under consideration, the final decision processor will determine if the Digraph Distribution score for that culture is within the range specified by the Under\_Di\_Threshold parameter<sup>1</sup>. Note that since there is no Digraph Distribution score calculated for the cultural affinity "Other",

For additional information regarding the range specified by the Under\_Di\_Threshold parameter, see section 3.2.9.4.2.5.

there is no Under\_Di\_Threshold parameter associated with Other, and this processing applies only to cultures included in the current name classifier (e.g. Arabic and Hispanic).

- 3.1.12.4.3.1. In the event that the Digraph
  Distribution score is in the range
  specified for the particular culture,
  processing continues to determine if
  there is enough additional evidence to
  identify the input name as belonging
  to that culture.
- 3.1.12.4.3.2. In the event that the Digraph
  Distribution score is not in the range
  specified for the particular culture,
  that cultural affinity is removed from
  further consideration for the input
  name.
- 3.1.12.4.4. For each culture still under consideration, the final decision processor will determine if the LID score for that culture is within the range specified by the Under\_LID\_Threshold parameter<sup>1</sup>.
  - 3.1.12.4.4.1. In the event that the LID score is in the range specified for the particular culture, the final decision processor will identify the input name as belonging to that culture.
  - 3.1.12.4.4.2. In the event that the LID score is not in the range specified for the particular culture, processing continues to determine if there is enough additional evidence to identify the input name as belonging to that culture.
- 3.1.12.4.5. For each culture still under consideration, the Final Decision Processor determines whether

<sup>&</sup>lt;sup>1</sup> For more information regarding the range specified by the Under\_LID\_Threshold parameter, see section 3.2.9.4:2.4.

the COB supplied with the input name is in the partition associated with the cultural affinity, as defined in the COB Proximity (COBPROX) Data Store.

- 3.1.12.4.5.1. In the event that the COB supplied with the input name is in the partition associated with the cultural affinity under consideration, the final decision processor will identify the input name as belonging to that culture.
- 3.1.12.4.5.2. In the event that the COB supplied with the query is not in the partition associated with the cultural affinity under consideration, that cultural affinity is removed from further consideration for the input name.
- 3.1.12.4.5.3. In the event that the COB supplied with the input name is Unknown (i.e. "XXX" in Legacy CLASS), the Final Decision Processor will identify the input name as belonging to the cultural affinity under consideration. Note that this is a conscious decision to err on the side of recall in the absence of adequate information (that is, to identify a name as belonging to a culture, perhaps erroneously, in an effort to avoid erroneously not identifying some input names as belonging to that culture). This is related to the other policy decisions to be made by CA, and may change based on those decisions.
- 3.1.12.4.6. A summarization of the processing performed by the final decision processor is contained in Figure 3-2.

03/19/98

97.X.

IF (Di\_Threshold - Digraph\_Distribution\_Score - Under\_Di\_Threshold >= 0) AND ((LID\_Threshold - LID\_Score - Under\_LID\_Threshold >= 0) OR (COB\_of\_input\_name is in partition OR COB\_of\_input\_name is Unknown))
THEN
Identify Input Name as belonging to the culture in question
END IF

3.1.12.5. Subordinates None.

ANC-E Language Analysis Systems, Inc.

#### 3.2. Data Decomposition

The data tables which underlie the Linguistically Informed Decision processor are crucial to the success of the algorithm. As discussed in 3.1.2.4.3, the linguistic data to be used are: High Frequency names, TAQ elements, Morphological elements and Ngrams. The entries for each of these linguistic sources will be associated, minimally, with a name field, a cultural group and a score. Also associated with the LID are control parameters. The Data entities accessed by the LID, as well as by other ANC-E Modules are depicted in Figure 3-3. This section describes in detail the data stores used by ANC-E. For examples of the type of information to be included in the data stores, see the detailed example in Appendix A.

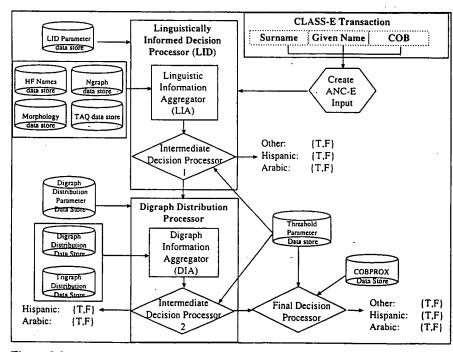

Figure 3-3

# 3.2.1. LID Parameter Data Store Data Decomposition

3.2.1.1. Identification

This data store is referred to as the LID Parameter Data Store.

3.2.1.2. Type

6.4.85

The LID Parameter Data Store is a data store that is accessed by the LID module.

3.2.1.3. Purpose

- 3.2.1.3.1. The LID takes factors such as HF names, Ngrams, TAQ particles, and Morphemes into account in determining the cultural affinity of the input name.
- 3.2.1.3.2. Although each of these factors is valuable, they should not all be given the same relative weight in determining the cultural affinity score of the input name.
- 3.2.1.3.3. Furthermore, as in all real-world applications, the data in the CLASS-E database is not "clean". That is, data elements are not always found in the expected positions. Therefore, it is common to find surname elements in the given name field, and vice versa. Since it is not always possible to determine whether a particular instance of "out-of-field" data is due to random factors influencing data entry procedures or to a name's being from a culture other than the one hypothesized, data found "out of position" should not be given as great a weight as data found in the canonical position.
- 3.2.1.3.4. The LID Parameter data store exists in order to allow for different weighting of evidence found by the LID based on the above factors without hard-coding the exact weighting scheme itself in the LID. This will allow for runtime finetuning and adjustments to ANC-E without the necessity of recompiling LID module code.

#### 3.2.1.4. Function

3.2.1.4.1. Table 3.2-1 contains a description of the data to be contained in the LID Parameter data store.

DATA NAME	DATA TYPE	DATA	POSSIBLE
DATAMME		WIDTH	VALUES
AGENT_NAME	character	10	(HFNAME,
AGENT_NAME	<b>4.1.4.</b>		TAQ,
.*			MORPHOLOGY,
			NGRAM}
NAMEFIELD	character	1	{G,S}
INFIELD_SCORE	integer	2	{1,2,, 10}
OUT OF FIELD_SCORE	integer	2	$\{1, 2,, 10\}$

**Table 3.2-1** 

- 3.2.1.4.2. The LID uses the information provided in this data store when calculating aggregate cultural affinity scores from the detailed scoring information returned by LIA.
  - 3.2.1.4.2.1. AGENT\_NAME indicates to which agent (function) the given INFIELD\_SCORE and OUT\_OF\_FIELD\_SCORE weightings apply.
  - 3.2.1.4.2.2. NAMEFIELD indicates whether the INFIELD\_SCORE and OUT\_OF\_FIELD\_SCORE weightings apply to the Given Name (G) or to the Surname (S).
  - 3.2.1.4.2.3. IN\_FIELD\_SCORE is the weighting to be applied to data elements' raw scores returned by the specified agent when found in the specified name field.
  - 3.2.1.4.2.4. OUT\_OF\_FIELD\_SCORE is the weighting to be applied to data elements' raw scores returned by the specified agent when found out of the specified name field.

- 3.2.1.4.2.4.1. For more information concerning IN\_FIELD and OUT\_OF\_FIELD attributes returned from individual agents via LIA, see 3.1.4.4.3.
- 3.2.1.4.2.4.2. For an example of scoring of an input name using raw scores returned by agents and the LID Parameters, see Figure 3-4.
- 3.2.1.5. Subordinates None.
- 3.2.2. High Frequency Name Data Store Data Decomposition
  - 3.2.2.1. Identification

This data store is referred to as the HF Name Data Store.

3.2.2.2. Type

The HF Name Data Store is a data store that is accessed by the HF Name Processor.

3.2.2.3. Purpose

The HF Name Data Store encodes the knowledge necessary for the HF Name Processor function of the LID to add information needed for the cultural identification of the input name.

3.2.2.4. Function

3.2.2.4.1. Table 3.2-2 contains a description of the data to be contained in the HF Name data store.

DATA TYPE	DATA WIDTH	POSSIBLE VALUES	
character	24	*	
character	1	{G,S }	
integer	1	{1,2,3,4,5}	
character	1	{H, A, O}	
	character character integer	· WIDTH  character 24  character 1  integer 1	

**Table 3.2-2** 

- 3.2.2.4.2. The HF Name Processor uses the information provided in this data store when gathering detailed HF name cultural affinity information to be returned to LIA. High frequency given names and surnames for each of the three target cultural groups will be listed in the high frequency data store.
  - 3.2.2.4.2.1. NAME indicates the literal string representation of the HF name.
  - 3.2.2.4.2.2. NAMEFIELD indicates whether the score listed for the HF name applies to the Given Name (G) or to the Surname (S).
  - 3.2.2.4.2.3. SCORE reflects the degree to which a name may be considered high frequency within the culture in question, and is the score assigned by the HF Name Processor when the HF name listed is found in the input name. For processing details, see section 3.1.4, High Frequency (HF) Name Processor Module Decomposition.
  - 3.2.2.4.2.4. CULTURE indicates the cultural affinity with which the given NAME-NAMEFIELD-SCORE combination is associated.
  - 3.2.2.4.2.5. A HF name string may appear in the HF Names Data Store multiple times if it is associated with multiple cultural affinities, or if it associated with a different frequency score in the given name and surname. In this instance, the correct score must be assigned for each CULTURE, NAMEFILED combination associated with the HF name in question.
    - 3.2.2.4.2.5.1. For an example of scoring of an input name using raw scores returned by agents and

# 3.2.2.5. Subordinates

None.

## 3.2.3. TAQ Data Store Data Decomposition

#### 3.2.3.1. Identification

This data store is referred to as the TAQ Data Store.

## 3.2.3.2. Type

The TAQ Data Store is a data store that is accessed by the TAQ Processor.

#### 3.2.3.3. Purpose

The TAQ Data Store encodes the knowledge necessary for the TAQ Processor function of the LID to add information needed for the cultural identification of the input name.

#### 3.2.3.4. Function

3.2.3.4.1. Table 3.2-3 contains a description of the data to be contained in the TAQ data store.

DATA NAME	DATA TYPE	DATA	POSSIBLE
	•	WIDTH	VALUES
TAQ	character	24	*
NAMEFIELD	character	1	{G,S,B}
SCORE	integer	10	{1,2,3,4,5}
CULTURE	integer	3	11,000

Table 3.2-3

ANC-E

3.2.3.4.2. The TAQ Processor uses the information provided in this data store when gathering detailed TAQ - cultural affinity information to be returned to LIA. TAQ values for each of the three target cultural groups will be listed in the TAQ data store.

> 3.2.3.4.2.1., TAQ indicates the literal string representation of the Title, Affix or Qualifier particle. Note that only free

Morphemes are included in the TAQ data store, so, by definition, all TAQs are implicitly bounded by white space.

- 3.2.3.4.2.2. NAMEFIELD indicates whether the score listed for the given TAQ particle applies to the Given Name (G), to the Surname (S), or to Both (B).
  - 3.2.3.4.2.2.1. In the event that the NAMEFIELD is listed as "B", the associated TAQ is defined as "in position" whether it is found in the given name or in the surname field in the input name, and is scored accordingly.
- 3.2.3.4.2.3. SCORE is a score for the given TAQ-NAMEFIELD-CULTURE combination. The TAQ scores will reflect the predictive value of the TAQ particle for the culture with which it is associated. This is the score assigned by the TAQ Processor when the TAQ particle listed is found in the input name. For processing details, see section 3.1.5, Title, Affix, Qualifier (TAQ) Processor Module Decomposition.
- 3.2.3.4.2.4. CULTURE indicates the cultural affinity with which the given TAQ-NAMEFIELD-SCORE combination is associated.
- 3.2.3.4.2.5. A TAQ particle may appear in the TAQ Data Store multiple times if it is associated with multiple cultural affinities. In this instance, the correct score must be assigned for each cultural affinity associated with the TAQ value in question.
  - 3.2.3.4.2.5.1. For an example of scoring of an input name using raw

scores returned by agents and the LID Parameters, see Figure 3-4.

#### 3.2.3.5. Subordinates

None.

3.2.4. Morphological Data Store Data Decomposition

#### 3.2.4.1. Identification

This data store is referred to as the Morphological Data Store.

## 3.2.4.2. Type

The Morphological Data Store is a data store that is accessed by the Morphological Processor.

#### 3.2.4.3. Purpose

The Morphological Data Store encodes the knowledge necessary for the Morphological Processor function of the LID to intelligently process the input name, evaluating evidence based on culturally-specific Morphemes, and adding this to information needed for the cultural identification of the input name.

#### 3.2.4.4. Function

3.2.4.4.1. Table 3.2-4 contains a description of the data to be contained in the Morphology data store.

DATA NAME	DATA TYPE	DATA WIDTH	POSSIBLE VALUES
) (ODDITE) (E	-1	24	*
MORPHEME	character	. 24	
NAMEFIELD	character	1	{G, S, B}
MORHTYPE	character	1	{E, P, S, I, A}
SCORE	integer	1	{1, 2, 3, 4, 5}
CULTURE	character	1	{A, H, O}

Table 3.2-4

3.2.4.4.2. The Morphological Processor uses the information provided in this data store when gathering detailed Morpheme - cultural affinity

information to be returned to LIA. Morpheme values for each of the three target cultural groups will be listed in the Morphological Data Store.

- 3.2.4.4.2.1. MORPHEME indicates the literal string representation of the Morpheme. Note that only bound Morphemes are included in the Morphological data store, so, by definition, all Morphemes are intended to be located as substrings of individual segments of the input name.
- 3.2.4.4.2.2. NAMEFIELD indicates whether the score listed for the given Morpheme applies to the Given Name (G), to the Surname (S), or to Both (B).
  - 3.2.4.4.2.2.1. In the event that the NAMEFIELD is listed as "B", the associated MORPHEME is defined as "in position" whether it is found in the given name or in the surname field in the input name, and is scored accordingly.
- 3.2.4.4.2.3. MORPHTYPE indicates the linguistic distribution of the MORPHEME.
  - 3.2.4.4.2.3.1. Prefixes (P) are substrings which begin in the first character position of a name segment.
  - 3.2.4.4.2.3.2. INFIXES (I) are substrings which begin in a character position in the name segment which is not the first, and end in a character position in the name segment that is not the last. They are substrings that are neither at the beginning nor the end of the name segment.

- 3.2.4.4.2.3.3. SUFFIXES (S) are substrings which end in the final character position of a name segment.
- 3.2.4.4.2.3.4. A MORPHEME for which the MORPHTYPE is indicated as EDGE (E) can be found as either a PREFIX or a SUFFIX in a name segment in the input name.
- 3.2.4.4.2.3.5. A MORPHEME for which the MORPHTYPE is indicated as ALL (A) can be found anywhere in a name segment in the input name.
- 3.2.4.4.2.3.6. MORPHEMEs that are found in positions other than those indicated by the corresponding MORPHTYPE are not assigned any points for the purpose of identifying the cultural affinity of the input name.
- 3.2.4.4.2.4. SCORE is a score for the given MORPHEME-NAMEFIELD-MORPHTYPE-CULTURE combination. The MORPHEME scores will reflect the predictive value of the Morpheme for the culture with which it is associated. This is the score assigned by the Morphological Processor when the Morpheme listed is found in the input name. For processing details, see section 3.1.6, Morphological Processor Module Decomposition.
- 3.2.4.4.2.5. CULTURE indicates the cultural affinity with which the given MORPHEME-MORPHTYPE-

NAMEFIELD-SCORE combination is associated.

3.2.4.4.2.6. A Morpheme may appear in the Morphological Data Store multiple times if it is associated with multiple cultural affinities, or if it can be associated with multiple values of NAMEFIELD and/or MORPHTYPE for a given cultural affinity. In this instance, the correct score must be assigned for each MORPHEME-MORPHTYPE-NAMEFIELD-CULTURE combination associated with the Morpheme in question.

3.2.4.4.2.6.1. For an example of scoring of an input name using raw scores returned by agents and the LID Parameters, see Figure 3-4.

3.2.4.5. Subordinates None.

- 3.2.5. Ngram Data Store Data Decomposition
  - 3.2.5.1. Identification

    This data store is referred to as the Ngram Data Store.
  - 3.2.5.2. Type

    The Ngram Data Store is a data store that is accessed by the
    - Ngram Processor.
      - The Ngram Data Store encodes the knowledge necessary for the Ngram Processor function of the LID to add evidence based on the distribution of culturally salient Ngrams to information needed for the cultural identification of the input name.
  - 3.2.5.4. Function

3.2.5.3. Purpose

3.2.5.4.1. Table 3,2-5 contains a description of the data to be contained in the Ngram data store.

DATA NAME	DATA TYPE	DATA WIDTH	POSSIBLE
			VALUES
NGRAM	character	10	*
NAMEFIELD	character		{G, S, B}
NGRAMTYPE	character	1	{E, P, I, S, A}
SCORE	integer	1 .	{1, 2, 3, 4, 5}
CULTURE	character	1	{A, H, O}

Table 3.2-5

- 3.2.5.4.2. The Ngram Processor uses the information provided in this data store when gathering detailed cultural affinity information to be returned to LIA. Ngram values for each of the three target cultural groups will be listed in the Ngram Data Store.
  - 3.2.5.4.2.1. NGRAM indicates the literal string representation of the Ngram. Note that all Ngrams are intended to be located as substrings of individual segments of the input name.
  - 3.2.5.4.2.2. NAMEFIELD indicates whether the score listed for the given Ngram applies to the Given Name (G), to the Surname (S), or to Both (B).
    - 3.2.5.4.2.2.1. In the event that the NAMEFIELD is listed as "B", the associated NGRAM is defined as "in position" whether it is found in the given name or in the surname field in the input name, and is scored accordingly.
  - 3.2.5.4.2.3. NGRAMTYPE indicates the linguistic distribution of the NGRAM.
    - 3.2.5.4.2.3.1. PREFIXES (P) are substrings which begin in the first character position of a name segment.

- 3.2.5.4.2.3.2. INFIXES (I) are substrings which begin in a character position in the name segment which is not the first, and end in a character position in the name segment that is not the last. They are substrings that are neither at the beginning nor the end of the name segment.
- 3.2.5.4.2.3.3. SUFFIXES (S) are substrings which end in the final character position of a name segment.
- 3.2.5.4.2.3.4. An NGRAM for which the NGRAMTYPE is indicated as EDGE (E) can be found as either a PREFIX or a SUFFIX in a name segment in the input name.
- 3.2.5.4.2.3.5. An NGRAM for which the NGRAMTYPE is indicated as ALL (A) can be found anywhere in a name segment in the input name.
- 3.2.5.4.2.3.6. NGRAMs that are found in positions other than those indicated by the corresponding NGRAMTYPE are not assigned any points for the purpose of identifying the cultural affinity of the input name.
- 3.2.5.4.2.4. SCORE is a score for the given NGRAM-NAMEFIELD-NGRAMTYPE-CULTURE combination. The NGRAM scores will reflect the predictive value of the Ngram for the culture with which it is

associated. This is the score assigned by the Ngram Processor when the given Ngram is found in the input name. For processing details, see section 3.1.7, Ngram Processor Module Decomposition.

- 3.2.5.4.2.5. CULTURE indicates the cultural affinity with which the given NGRAM-NGRAMTYPE-NAMEFIELD-SCORE combination is associated.
- 3.2.5.4.2.6. An Ngram may appear in the Ngram
  Data Store multiple times if it is
  associated with multiple cultural
  affinities, or if it can be associated with
  multiple values of NAMEFIELD
  and/or NGRAMTYPE for a given
  cultural affinity. In this instance, the
  correct score must be assigned for each
  NGRAM-NGRAMTYPENAMEFIELD-CULTURE
  combination associated with the
  Ngram in question.
  - 3.2.5.4.2.6.1. For an example of scoring of an input name using raw scores returned by agents and the LID Parameters, see Figure 3-4.

3.2.5.5. Subordinates None.

Figure 3-4

# 3.2.6. Digraph Distribution Data Store Data Decomposition

## 3.2.6.1. Identification

This data store is referred to as the Digraph Data Store.

#### 3.2.6.2. Type

The Digraph Data Store is a data store that is accessed by the Digraph Distribution Processor.

# 3.2.6.3. Purpose

The Digraph Data Store encodes the knowledge necessary regarding the statistical distribution of digraphs within a given culture. It is this information that drives the Digraph Distribution Processor.

# 3.2.6.4. Function

3.2.6.4.1. Table 3.2-6 contains a description of the data to be contained in the Digraph data store.

DATA NAME	DATA TYPE	DATA WIDTH	POSSIBLE VALUES
DI	character	2	*
SCORE	long	3.4	{-50.0000 - +50.0000}
CULTURE	character	1	{A, H}

**Table 3.2-6** 

- 3.2.6.4.2. The Digraph Processor uses the information provided in this data store when determining the contribution that the distribution of digraphs in the input name will have in determining the cultural affinity of that name Digraph Distribution statistics will be listed in the Digraph Data Store for each of the specific cultures being identified. That is, in the current implementation, Digraph Distribution statistics will be listed for Arabic and Hispanic; but not for "Other".
  - 3.2.6.4.2.1.1. DI indicates the literal string representation of the digraph. Note that digraphs may include all alphabetical characters as well as the word-boundary character "#".
  - 3.2.6.4.2.2. SCORE reflects the predictive value of the digraph for the culture with which it is associated. This is the score used by the Digraph Distribution Processor when the given digraph is found in the input name. For processing details, see section 3.1.9, Digraph Distribution Processor Module Decomposition.
  - 3.2.6.4.2.3. CULTURE indicates the cultural affinity with which the given DI-SCORE combination is associated.

3.2.6.5. Subordinates None.

#### 3.2.7. Trigraph Distribution Data Store Data Decomposition

#### 3.2.7.1. Identification

This data store is referred to as the Trigraph Data Store.

#### 3.2.7.2. Type

The Trigraph Data Store is a data store that is accessed by the Digraph Distribution Processor. The Digraph Distribution Processor takes initial and final trigraphs into account in producing a digraph distribution score for the input name.

#### 3.2.7.3. Purpose

The Trigraph Data Store encodes the knowledge necessary regarding the statistical distribution of trigraphs within a given culture. This information is taken into account in the Digraph Distribution Processor, since name boundaries tend to be highly indicative of the cultural affinity of the name.

#### 3.2.7.4. Function

3.2.7.4.1. Table 3.2-7 contains a description of the data to be contained in the Trigraph data store.

DATA NAME	DATA TYPE	DATA WIDTH	POSSIBLE VALUES
TRI	character	3	*
SCORE	long	3.4	{-50.0000 -
	, and the second		+50.0000}
CULTURE	character	1	{A, H}

Table 3.2-7

3.2.7.4.2. The Digraph Processor uses the information provided in this data store when determining the contribution that the distribution of initial and final trigraphs in the input name will have in determining the cultural affinity of that name Trigraph Distribution statistics will be listed in the Trigraph Data Store for each of the specific cultures being identified. That is, in the current implementation, Trigraph Distribution statistics will be listed for Arabic and Hispanic, but not for "Other".

- 3.2.7.4.2.1. DI indicates the literal string representation of the trigraph. Note that trigraphs may include all alphabetical characters as well as the word-boundary character "#".
- 3.2.7.4.2.2. SCORE reflects the predictive value of the trigraph for the culture with which it is associated. This is the score used by the Digraph Distribution Processor when the given trigraph is found in the input name. For processing details, see section 3.1.9, Digraph Distribution Processor Module Decomposition.
- 3.2.7.4.2.3. CULTURE indicates the cultural affinity with which the given DI-SCORE combination is associated.
- 3.2.7.4.3. Trigraph Distribution statistics for only initial and final trigraphs will be included in the Trigraph Data Store.
- 3.2.7.5. Subordinates

None.

- 3.2.8. Digraph Distribution Processor Parameter Data Store Data Decomposition
  - 3.2.8.1. Identification

This data store is referred to as the Digraph Processor Parameter Data Store.

3.2.8.2. Type

The Digraph Processor Parameter Data Store is a data store that is accessed by the Digraph Distribution Processor.

3.2.8.3. Purpose

The Digraph Processor Parameter Data Store contains adjustments that must be made to the digraph distribution scores computed by the Digraph Distribution Processor due to the fact that some cultures are over-represented in the digraph model.

#### 3.2.8.4. Function

3.2.8.4.1. Table 3.2-8 contains a description of the data to be contained in the Trigraph data store.

DATA NAME	DATA TYPE	DATA WIDTH	POSSÍBLE VALUES
SKEW	integer	3	(-999 - +999)
CULTURE	character	1	{A, H}

**Table 3.2-8** 

- 3.2.8.4.2. The Digraph Processor uses the information provided in this data store when determining the final digraph distribution score to assign to the input name. A SKEW will be specified in the Digraph Processor Parameter Data Store for each of the specific cultures being identified. That is, in the current implementation, a SKEW will be listed for Arabic and Hispanic, but not for "Other".
  - 3.2.8.4.2.1. SKEW indicates the value to be added to or subtracted from the raw digraph distribution score by the digraph distribution processor to level data distribution differences.
  - 3.2.8.4.2.2. CULTURE indicates the cultural affinity with which the given SKEW is associated.
- 3.2.8.5. Subordinates None.
- 3.2.9. Threshold Parameter Data Store Data Decomposition
  - 3.2.9.1. Identification

This data store is referred to as the Threshold Parameter Data Store.

3.2.9.2. Type

The Threshold Parameter Data Store is a data store that is accessed by the Intermediate Decision Processor 1 (IDP1),

the Intermediate Decision Processor 2 (IDP2), and the Final Decision Processor.

#### 3.2.9.3. Purpose

The Threshold Parameter Data Store contains information regarding thresholds that must be met in order for the input name to be identified as belonging to a particular target culture.

#### 3.2.9.4. Function

3.2.9.4.1. Table 3.2-9 contains a description of the data to be contained in the Threshold Parameter data store.

•		•	•
DATA NAME	DATA TYPE	DATA WIDTH	POSSIBLE
			VALUES
CULTURE	character	1	{A, H, O}
LID_THRESHOLD	integer	3	{0 - 999}
DI_THRESHOLD	float	3.4	{-999.9999 -
<del>-</del>			+999.9999}
UNDER_LID_	integer	3	{0 - 999}
THRESHOLD			
UNDER_DI_	integer	3	{0 - 999}
THRESHOLD	•	•	

**Table 3.2-9** 

ege (%)

3.2.9.4.2. The three "decision processor" modules (IDP1, IDP2, and the Final Decision Processor) use the information provided in this data store when determining whether enough information has been accumulated to identify the input name as belonging to a particular culture.

LID\_THRESHOLD and

UNDER\_LID\_THRESHOLD data values will be specified in the Threshold Parameter Data Store for each of the cultures being identified, including "Other". DI\_THRESHOLD and UNDER\_DI\_THRESHOLD values will be specified for specific cultures only (i.e. Hispanic and Arabic).

- 3.2.9.4.2.1. CULTURE indicates the cultural affinity with which the given threshold is associated.
- 3.2.9.4.2.2. LID\_THRESHOLD is used by IDP1 in determining whether enough information has been accumulated to identify the input name as belonging to a particular culture. For processing information, see section 3.1.8, Intermediate Decision Processor 1 (LID Decision) Module Decomposition.
- 3.2.9.4.2.3. DI\_THRESHOLD is used in IDP2 in determining whether enough information has been accumulated to identify the input name as belonging to a particular culture. For processing information, see section 3.1.11, Intermediate Decision Processor 2 (Digraph Decision) Module Decomposition.
- 3.2.9.4.2.4. UNDER\_LID\_THRESHOLD is used by the Final Decision Processor, and indicates the amount by which a name can fall short of the LID\_THRESHOLD and still be considered for membership in a particular culture, provided that other criteria are met. As such, UNDER\_LID\_THRESHOLD defines a range of values (between the UNDER\_LID\_THRESHOLD and the LID\_THRESHOLD) that, when considered in conjunction with other evidence, can result in the input name's being identified as belonging to the culture in question. For processing information see section 3.1.12, Final Decision Processor Module Decomposition and Figure 3-, 2.

3.2.9.4.2.5. UNDER\_DI\_THRESHOLD is used by the Final Decision Processor, and indicates the amount by which a name can fall short of the DI\_THRESHOLD and still be considered for membership in a particular culture, provided that other criteria are met. As such, UNDER\_DI\_THRESHOLD defines a range of values (between the UNDER\_DI\_THRESHOLD and the DI\_THRESHOLD) that, when considered in conjunction with other evidence, can result in the input name's being identified as belonging to the culture in question. For processing information, see section 3.1.12, Final Decision Processor Module Decomposition and Figure 3-

# 3.2.9.5. Subordinates None.

#### 3.2.10. COB Proximity (COBPROX) Data Store Data Decomposition

#### 3.2.10.1. Identification

This data store is referred to as the COBPROX Data Store.

#### 3.2.10.2. Type

The COBPROX Data Store is a data store that is accessed by the Final Decision Processor.

## 3.2.10.3. Purpose

The COBPROX Data Store contains information enabling the Final Decision Processor to determine which COBs are to be considered as related when determining the cultural affinity of the input name. For processing information, see section 3.1.12.4.5 and Figure 3-2.

## 3.2.10.4. Function

3.2.10.4.1.1. ANC-E will use the CLASS-E COBPROX Data Store ("partition table") to fill this function.

3.2.10.5. Subordinates None.

# SOFTWARE DESIGN DESCRIPTION FOR THE ARABIC NAME SEARCH ALGORITHM FOR CLASS - E (ANA - E)

INTRODUCTION

#### 1.1. Purpose

The variation that can occur in the transcription of Arabic names into roman representation poses formidable problems for retrieval systems with very large databases that depend solely on standard string-comparison techniques. For example, the following names are transcription variants of the same name: SALEHUDDINE, IMHEMED and SAALAH EL DEEN, MUHAMMED. The significant differences in their spellings and in the distribution of white space would virtually preclude any possibility of identifying these names as similar enough to be candidates for retrieval if the usual techniques were applied. The task, then, is to capture the relatedness of these names and to incorporate the insights into their commonality into the retrieval system.

Arabic names are made up of a Given Name (GN) (usually one, although compound names may occur: SAMIR; MOHAMAD ALI) and a string of familial (paternal) relations following the GN (ABD EL KADEER SAMIR ABD EL LATIF). The string following the GN is generally made up of GNs which are taken from the father, grandfather and other relations. Only in rare cases can any of these segments be identified as a SN, i.e., a name used by every member of the family to signal family membership. The full string following the GN provides crucial information about the individual that is lost if it is sometimes in the GN field and sometimes in the SN field. So, positioning names that occur after the first GN in the SN field provides the opportunity for better matches.

### 1.2. Scope

In 1996, LAS proposed an initial solution to the problem, the salient feature of which was to level spelling differences and thereby generate one representation for the myriad spellings of a single name. This process is known as *regularization*, a technique that was implemented in the Legacy CLASS system as Legacy ANA. Legacy ANA is a preprocessing module that feeds into the Legacy CLASS search system. The general characteristics of Legacy ANA are:

1) Both query and add procedures are identical for the Legacy ANA system.

ANA-E Language Analysis Systems, Inc.

- 2) A rudimentary Arabic name identifier (ANI) determines if an input name qualifies for handling by the Legacy ANA algorithm. All names that qualify for Legacy ANA handling are also sent to the generic processing module provided by Legacy CLASS and to the DOB processor, when appropriate.
- 3) A set of regularization rules is applied to the Arabic input name, leveling the spelling differences of the name segments to the most common representation of the input name. IMHEMED and MUHAMMED will both be regularized to the form MUHAMAD, for example. Some title/affix/qualifier information may also be removed from the name to focus on the name stem. The regularization rules are rewrite rules that use notation developed solely for this processor. The rule engine necessary for implementation of the regularization rules was also developed specifically to handle the Legacy ANA regularization rules. The output of the regularization component is a regularized form of the input name.
- 4) The output of the regularization component (the regularized form of the name) serves as the input to the generic CLASS search system. CLASS produces standard compressed-name keys, but on the regularized form that is the output of Legacy ANA. CLASS accesses the database records through the keys on the regularized form. (The keys are generated for both queries and adds and are stored with the record when a record is added to the database.)
- 5) A digraph match is then performed on the regularized record and query forms to determine name similarity. The match criteria are those of CLASS.

The ANA-E system is an enhancement of the Arabic name search system that was developed by LAS for the Legacy CLASS system. The principle of name regularization remains the same in ANA-E, although the design and approach of ANA-E are different in a number of important ways.

- An independent Name Classifier (ANC-E) has been developed. (The ANC-E design description is provided as Attachment A in LAS Linguistic Memo CT970044, May 30, 1997) ANC-E will direct input names to the Arabic and/or Hispanic processors. Its functionality is far more sophisticated than the Arabic name typer (ANI). All records will also be directed to the CN pipe of CLASS-E and to the DOB pipe, if appropriate.
- 2) A significant amount of preprocessing of the name takes place in ANA-E that recognizes the unique character of Arabic names, focusing on the leftmost GN as the most stable element in the name and rejoining all other GN segments with their SN partners.
- 3) The regularization rules and rule engine have changed. The rules are represented in standard regular expressions and the format has changed. The rule engine uses different match techniques, is much simpler in its implementation and therefore can be easily applied to other rule sets.
- 4) The output of the regularization rules is a computationally viable form, one that may not be the most common representation of a name (as was a requirement of Legacy ANA).

ANA-E Language Analysis Systems, Inc.

- 5) The new ANA-E rule language has already allowed a dramatic increase in the amount of regularization that takes place. For those records that qualify as Arabic, a decrease of 13% in the number of different regularized forms from Legacy ANA (as of March 1997) to the proposed ANA-E regularization rules demonstrates the greater flexibility of the ANA-E language. The system must therefore accommodate fewer distinct name-segments, reducing processing time and increasing the scope of retrieval.
- 6) Arabic-specific keys have been generated to account for the nature of Arabic names and at the same time permit some unpredictable variation. The regularization rules account for much of the predictable variation in names but are only incidentally able to accommodate unpredictable variation (e.g., error).
- Retrieval is based on keys that represent a class of pre-determined variants of a name segment and are formed from the GN1 and SN segments.
- Gender has been added as a search criterion to reduce the occurrence of crossed-gender retrievals.
- 9) The filtering techniques used in ANA-E demonstrate much greater granularity and sensitivity to Arabic-specific name characteristics.

The CLASS-E system will support several concurrent record search processes. The Multi-Pipe Architecture (MPA) already in place supports the generic-CLASS search process and a distinct Date-of-Birth process. (Because the Legacy ANA system serves as a preprocessing module that feeds into the generic-CLASS processing pipe, Legacy ANA is not characterized as a separate search pipe.)

In CLASS-E the Multi-Pipe Architecture will be extended to include a distinct Arabic processing pipe, a distinct Hispanic processing pipe as well as perhaps others in the future. An input name may be submitted to more than one processing pipe. It is a business decision of CA/EX/CSD to determine to which and how many pipes to pass a given input name. It is suggested that names classified as Arabic by the Advanced Name Classifier for CLASS-E (ANC-E) be submitted to multiple processors: the generic CLASS-E processing pipe, the DOB processing pipe and the ANA-E processing pipe.

# 2. MODULE DECOMPOSITION

475

- 2.1. The Arabic Name Search Algorithm for CLASS-E (ANA-E) will consist of three primary components (see pages 6-9 for graphic representations of these components):
  - the Arabic Pre-Processor (APP),
  - the Arabic Search Engine (ASE), and
  - the Arabic Filter and Sorter (AFS).

### 2.2. ARABIC PRE-PROCESSOR MODULE DECOMPOSITION

#### 2.2.1. Identification

This module is known as the Arabic Pre-Processor (APP).

#### 2.2.2. Type

The APP is the first programming module in the larger ANA-E algorithm and consists of subordinate functions that manipulate the name segments in various ways to prepare the name for creation of search keys by Arabic Search Engine.

#### -2.2.3. Purpose

Because of the significant variation that can occur in names that have been romanized from the original Arabic script, Arabic names will benefit from attempts to level the spelling differences. In addition, the standard format of an Arabic name is Given Name followed by a string of segments that indicate familial relations. In many countries, none of these segments functions as what is standardly referred to as a *surname*. What is determined to be a Surname for purposes of a CLASS retrieval (i.e., what is placed in the Surname field) is therefore quite arbitrary. Arabic names will consequently benefit from movement of name segments that would contribute to a potential match.

### 2.2.4. Function

- 2.2.4.1. The Arabic Pre-Processor (APP) will accept as input any name that has been identified as Arabic by the Advanced Name Classifier for CLASS-E (ANC-E) and will prepare a name for the Arabic Search Engine by applying Arabic regularization rules to the name segments and reorganizing the name according to Arabic naming principles.
- 2.2.4.2. The APP can alternatively create a name object that "knows" characteristics about itself and collects information as it proceeds through the processing functions.

### 2.2.5. Subordinates

- Arabic Name Regularizer (ANR)
- Arabic TAQ Processor (ATP)
- Arabic Data Evaluator (ADE)
- Arabic Segment Positioner (ASP)
- Arabic Gender Identifier (AGI)

### 2.3. ARABIC NAME REGULARIZER MODULE DECOMPOSITION

#### 2.3.1. Identification

This module will be known as the Arabic Name Regularizer (ANR) and will consist of one subordinate processor, the Arabic Rule Engine, which will access and apply the rules in one data store, the Arabic Regularization Rules (ARR) Data Store.

### 2.3.2. Type

The ANR is a program that

- will operate on a full surname string and a full given name string of an add or query record,
- will generate a regularized form for each name segment or string of name segments to which the regularization rules have applied, and
- will submit the regularized form to other functions in the APP to continue to prepare the name for submission to the Arabic Search Engine.

#### 2.3.3. Purpose

والماقلية

....

The transcription of Arabic names from their native format (Arabic script) to the roman alphabet is highly variable; few, if any, transcription standards exist. Such rampant variation poses significant problems for string matching and retrieval systems; there are often too many characters that differ to effect a retrieval in character-based retrieval systems. For example, MUHAMMAD and IMHEMED are roman spellings of the same name; that is, they are represented by the same string of characters in the Arabic script. Leveling the differences in roman spelling, wherever possible, would improve record retrieval dramatically.

#### 2.3.4. Function

The ANR applies a set of regularization rules (ARR) to the surname and to the given name through the Arabic Rule Engine and produces a regularized form for any name segment or string of segments to which the rules can apply.

### 2.3.5. Subordinates

The ANR consists of one subordinate function, the Arabic Rule Engine, which accesses the Arabic Regularization Rule Data Store.

#### 2.4. ARABIC RULE ENGINE MODULE DECOMPOSITION

### 2.4.1. Identification

This function is known as the Arabic Rule Engine (ARE).

### 2.4.2. Type

The ARE is a program that attempts to apply transformation rules to an input string of characters and to effect a change in that string.

### 2.4.3. Purpose

- 2.4.3.1. The development of rules that are implemented in standard and readily accessible regular expressions allows for use of a less idiosyncratic rule engine than the one developed for Legacy ANA. (See Arabic Regularization Rule Data Store, Section 3.3).
- 2.4.3.2. The Arabic Regularization Rules (ARR) require an implementation module to effect the changes specified in the rules. The ARE plays that role.
- 2.4.3.3. The ARE replaces the rule engine developed for Legacy ANA. It is simpler and more generic and can be used for other rule implementations.
- 2.4.3.4. The ARR are more easily altered and reviewed.

#### 2.4.4. Function

- 2.4.4.1. The ARE accepts a full surname (SN) or full given name (GN) string as input.
- 2.4.4.2. The ARE will add a white space to the beginning of the SN or GN string that it accepts to serve as boundary markers.
- 2.4.4.3. The ARE scans the input string from left to right and attempts to match the Match Context of a rule.
- 2.4.4.4. If the ARE is able to identify a Match Context, it checks to see if the Pre- and Post-Contexts specified in the rule are present.
  - 2.4.4.4.1. If the Pre- and Post-Contexts specified in the rule match, then the ARE applies the rule and makes the specified change in the Match Context, producing the Output.
  - 2.4.4.4.2. The ARE then returns to the top of the rule set and attempts to identify a Match Context beginning with the character immediately following the previous Match Context.
- 2.4.4.5. If no match is found, the ARE moves to the Match Context of the next rule.
- 2.4.4.6. If no rule has fired, the default rule applies: the character output is the character itself. E.g.,  $S \rightarrow S$

### 2.4.4.7. Arabic Regularization Rules (ARR)

- 2.4.4.7.1. The ARRs are written as regular expressions and use, for the most part, regular expression notation. See Section 3.3 for ARR details.
- 2.4.4.7.2. The ARRs use defined metasymbols.
- 2.4.4.7.3. The ARE must be able to recognize all regular expression notation and metasymbols of the ARR and implement them.

ANA-E Language Analysis Systems, Inc.

### 2.4.4.7.4. ARRs have the format:

Figure 1: Format: Arabic Regularization Rule

PRE-CONTEXT | MATCH CONTEXT | POST-CONTEXT | → OUTPUT

### 2.4.4.7.5. Rule Ordering

- 2.4.4.7.5.1. Rule ordering is important because the **first** rule for which the ARE finds a Match Context (and the Pre- and Post-Contexts match as well) will apply. Once the rule has applied to the Match Context, no other rules will apply to it: *No* following rule will then fire on that Match Context.
  - 2.4.4.7.5.1.1. The rules must have internal ordering based on the Match Context only.
  - 2.4.4.7.5.1.2. Rules may intrude in the ordering of the Match Context if they are applicable to another phenomenon.
    - 2.4.4.7.5.1.2.1. For example, an MI  $\rightarrow$  NE rule will need to precede an M  $\rightarrow$  N rule or the MI  $\rightarrow$  NE will never apply.
    - 2.4.4.7.5.1.2.2. A rule that applies to a Match Context where A → AW could intervene between the "M" rules and have no effect on the order of application of the "M" rules.
    - 2.4.4.7.5.1.2.3. In general, rules with longer character strings in the Match Context need to precede rules with shorter character strings.
    - 2.4.4.7.5.1.2.4. Care must be taken when rules have symbols for optional characters, for example. The ordering of an M?L rule (a rule that can apply to ML or L) must be carefully placed with respect to other rules that apply to M and L.
- 2.4.4.7.5.2. The Output of one rule does *not* form the input to another rule.

- 2.4.4.7.5.2.1. Only one rule applies to a character or character string that matches a Match Context.
- 2.4.4.7.5.2.2. The first rule that matches all three contexts in the Match, Pre- and Post- Context order is applied.
- 2.4.4.7.5.2.3. The Output of a rule cannot then be changed.
- 2.4.4.7.5.2.4. Rules must be written so that they stand alone: rules are not interdependent.
- 2.4.4.7.5.3. If the ARE is able to match the Match Context, the Pre- and Post-Contexts are examined.
  - 2.4.4.7.5.3.1. If the Pre- and Post-Contexts both match, the ARE effects the change in the Match Context indicated in the OUTPUT.
    - 2.4.4.7.5.3.1.1. The next available context in the input string to be considered for a match immediately follows the previous *Match Context*.
    - 2.4.4.7.5.3.1.2. For example, if HEIMER is the input string and a rule applies to HEIM to make it GIM, the next available context for consideration is the E of ER (following HEIM). If an E rule is to apply, it can only apply to the *second* E, not that of the previous Match Context (HEIM).
    - 2.4.4.7.5.3.1.3. The Output of a previous rule cannot be the Pre- or Post-Context of a following rule.
  - 2.4.4.7.5.3.2. The rule is applied only if the ARE is successful in matching the Match Context and the Pre- and Post-Contexts.
- 2.4.4.7.6. There is no backtracking in the ARE.
- 2.4.4.7.7. The output of successful application of rule(s) by the ARE is a regularized Arabic form. The output of the ARE can be in any string form (e.g., binary, regular expression, characters).
- 2.4.4.8. Subordinates

None.

### 2.5. ARABIC TAQ PROCESSOR MODULE DECOMPOSITION

### 2.5.1. Identification

This function is known as the Arabic TAQ Processor (ATP).

### 2.5.2. **Type**

The ATP is a function that identifies titles (T), affixes (A) and qualifiers (Q), as specified in the Arabic TAQ Data Store, and implements the disposition indicated in that table.

### 2.5.3. Purpose

Arabic names frequently contain peripheral name elements, such as ABDEL, ABU, AL. Matching on these segments is not generally useful; the name segments with information value are the name stems, RAHMAN, SAYED, HANAWI. Removal of or disregard for the peripheral name elements allows more emphasis to be placed on the name stems.

### 2.5.4. Function

- 2.5.4.1. The ATP will access the Arabic TAQ Data Store (ATD) to identify titles (e.g., USTAAZ), affixes (e.g., EL DIN) and qualifiers (Q) that occur in the regularized name.
- 2.5.4.2. The ATP will tag as a T, P, I, S, or Q any such segments found in the name, as specified in the ATD.
  - 2.5.4.2.1. The ATP will scan the full SN or GN field for any TAQ segments.
  - 2.5.4.2.2. If the ATP identifies a segment, it will tag the segment with the ID NO and disposition, as indicated in the ATD.
  - 2.5.4.2.3. If the following segment is also a TAQ segment, it will tag the segment with the ID\_NO and disposition, as indicated in the ATD.
  - 2.5.4.2.4. This will continue until all *consecutive* TAQ segments have been tagged.
  - 2.5.4.2.5. When the ATP encounters a following segment that is not a TAQ segment, it will treat that segment as a stem.
    - 2.5.4.2.5.1. Each TAQ segment identified up to that point will be given the TAQ\_TYPE P (prefix) and each will be associated and stored with the following stem.
  - 2.5.4.2.6. The ATP will move to the next segment following the stem and will repeat the TAQ identification process.
    - 2.5.4.2.6.1. The ATP will tag all TAQ segments with the ID\_NO and disposition.
    - 2.5.4.2.6.2. When the ATP encounters a stem, it will tag each TAQ segment (not yet associated with a stem) with the TAQ\_TYPE P and will associate and store each TAQ segment with the following stem.

- 2.5.4.2.7. If the ATP encounters a TAQ segment (or segments) that has no following stem, it will access the ATD to determine if the TAQ type is a Suffix (S).
  - 2.5.4.2.7.1. If the TAQ has a TAQ\_TYPE S, the TAQ will be associated and stored with the *preceding* stem.
  - 2.5.4.2.7.2. The preceding stem may already have prefixal TAQs.
  - 2.5.4.2.7.3. If the TAQ type is not equal to S, the TAQ will be tagged a Stranded Affix.
- 2.5.4.3. The ATP will process any TAQ segments identified according to the treatment indicated in the ATD. (See Section 3.4.)
  - 2.5.4.3.1. Treatment options include DELETE and DISREGARD.
  - 2.5.4.3.2. **DELETE** means that the segment is completely disregarded in the remainder of the name search process and contributes marginal information to the filtering process. (N.B. The segment is not deleted from the record.)
  - 2.5.4.3.3. **DISREGARD** means that the segment is disregarded in the remainder of the name search process but contributes to the evaluation of the name in the filtering processes.

### 2.5.4.4. TAQ Tag

- 2.5.4.4.1. The TAQ tag will reference the ID\_NO of the TAQ.
- 2.5.4.4.2. The TAQ tag will reference the indicated treatment of the TAQ segment.
- 2.5.4.4.3. The TAQ tag will be associated with a name stem, unless marked as a Stranded Affix.
- 2.5.4.4.4. Surnames containing the prefix AL (e.g., AL IDRISI) will be specially marked.
- 2.5.4.5. The TAQ tag will assist in the sorting of records (see Section 2.12, the Arabic Filter and Sorter (AFS)).

#### 2.5.5. Subordinates

None.

### 2.6. ARABIC DATA EVALUATOR MODULE DECOMPOSITION

#### 2.6.1. Identification

This function is known as the Arabic Data Evaluator (ADE).

### 2.6.2. Type

The ADE is a function that "corrects" data entry errors by generating one or more alias records.

### 2.6.3. Purpose

Arabic names are conventionally a Given Name followed by a string of (usually paternal) relationships, elements of which are routinely deleted. Some data entry operators have apparently attempted to capture the fact that the Arabic name is closer to a single name string by entering XXX into the Given Name field, cf., presumably the XXX permitted in the COB or DOB fields. Because XXX is not a conventional representation of any Given Name information, it interferes with the name search and will be altered.

### 2.6.4. Function

The ADE will determine if the leftmost Given Name segment (only) is XXX. If so, it will change that string to FNU and generate an alias add record or query.

### 2.6.5. Subordinates.

None.

### 2.7. ARABIC SEGMENT POSITIONER MODULE DECOMPOSITION

#### 2.7.1. Identification

This function is known as the Arabic Segment Positioner (ASP).

#### 2.7.2. Type

The ASP is a processing module that operates on the preprocessed, regularized name and moves name segments from the Given Name field into the Surname field. Alias records will be produced to reflect format changes.

### 2.7.3. Purpose

Arabic names are made up of a Given Name (GN) (usually one, although compound names may occur: SAMIR; MUHAMAD ALI) and a string of familial (paternal) relations following the GN (ABD EL KADEER SAMIR ABD EL LATIF). This string is generally made up of GNs which are taken from the father, grandfather and other relations. In most cases, none of these segments be identified as a Surname, i.e., a name used by every member of the family to signal family membership. The full string following the GN provides crucial information about the individual that is lost if it is sometimes in the GN field and sometimes in the SN field. So, positioning names that occur after the first GN in the SN field provides the opportunity for better matches.

#### 2.7.4. Function

2.7.4.1. The ASP will move all segments to the right of the leftmost GN (GN1) (in the preprocessed; regularized name) to the leftmost SN position, preserving the order of the moved segments.

Figure 2: Movement of Segments into SN Field

FARUK, MUHAMAD SAMIR ABDULA	<b>→</b>	SAMIR ABDULA FARUK, MUHAMAD

2.7.4.2. The leftmost Given Name (GN1) segment will not be moved into the Surname field *except* 

- a) if there is one and only one GN segment and
- b) if there is one and only one SN segment which has been tagged as having the prefix AL,
- then the ASP will generate an alias record with the SN and GN inverted.

Figure 3: Inversion of SN and GN with AL in the SN Field

	SURNAME	GN1	
į	(AL) IDRISI	YUSEF	→
	YUSEF	(AL) IDRISI	

2.7.4.3. The GN1 may be a name segment, an initial, or FNU. (See Section 2.9, the Arabic Search Engine (ASE) for additional information.)

### 2.7.5. Subordinates

None.

### 2.8. ARABIC GENDER IDENTIFIER MODULE DECOMPOSITION

### 2.8.1. Identification

This function is known as the Arabic Gender Identifier (AGI).

### 2.8.2. Type

- 2.8.2.1. The AGI is a function that will apply after the ANR has produced a regularized representation of the input name and the Arabic Segment Positioner (ASP) has moved all GN segments other than the GN1 into the SN field.
- 2.8.2.2. For the AGI to derive record gender, the data input operator will need to supply gender for each record added to the database and for each query during the data entry process.

### 2.8.3. Purpose

- 2.8.3.1. Crossed-gender records are of little value to the system user.
- 2.8.3.2. Arabic gender is reliably predictable from the GN1.
- 2.8.3.3. Records that have crossed gender will receive lowered match values during the filtering and sorting process.
- 2.8.3.4. Record gender requires gender validation from two sources: gender received during the data entry process and predictable gender associated with Arabic names.
- 2.8.3.5. Record gender reduces the chance of associating gender with a name that may be misspelled.

### 2.8.4. Function

- 2.8.4.1. The AGI will derive the record gender for all record adds and queries.
  - 2.8.4.1.1. For each query and add name, the AGI will derive record gender from user-supplied gender input and from the gender that has been assigned to the GN1.
  - 2.8.4.1.2. A *minimum* of two gender indicators is required for a gender assignment of M or F.
- 2.8.4.2. For record adds, gender received as input from the data entry process will be stored with the record.
- 2.8.4.3. For record queries, the user will input the gender of the applicant at query time.
- 2.8.4.4. For both adds and queries, the AGI will access the Arabic Name Type Data Store (ANT) and will assign the gender value to the GN1 segment, as indicated in the ANT (GENDER). (See Section 3.5.)
  - 2.8.4.4.1. If the name is present in the ANT, the gender associated with the name segment will be compared to the data entry gender.
    - 2.8.4.4.1.1. If the gender indicators match, the matching value will become the record gender.

ANA-E Language Analysis Systems, Inc.

# 2.8.4.4.1.2. If the gender indicators do not match, the record gender will be Unknown (U).

2.8.4.4.2. If the name is not present in the ANT, the record gender will be marked as Unknown (U).

#### 2.8.5. Subordinates

None.

### 2.9. ARABIC SEARCH ENGINE MODULE DECOMPOSITION

#### 2.9.1. Identification

This module is known as the Arabic Search Engine (ASE).

### 2.9.2. Type

The ASE is a processing module that accepts the output of the Arabic Preprocessor (APP), generates retrieval keys through the Arabic Key Generator, retrieves candidate records from the database based on the keys and submits those candidate records to the Arabic Filter and Sorter (AFS) Module.

### 2.9.3. Purpose

The regularized, repositioned names generated by the APP will be, in general, a representation of the canonical form of the Arabic name. The search process will benefit from focus on the canonical form of the Arabic name.

### 2.9.4. Function

The ASE will retrieve records from the database whose stored keys match the keys generated for the query record.

### 2.9.5. Subordinates

The ASE has one subordinate module:

Arabic Key Generator

### 2.10. ARABIC KEY GENERATOR MODULE DECOMPOSITION

#### 2.10.1. Identification

This function is known as the Arabic Key Generator (AKG).

### 2.10.2. Type

The AKG is a function that will form keys from the GN1 and each SN segment of the preprocessed, regularized name for both record adds and queries.

### 2.10.3. Purpose

In order to reduce the number of records that must be compared by the Arabic Filter and Sorter Module, it is desirable to subset the Arabic database. (About 500,000 records have qualified as Arabic through the ANI name typing process and it is assumed that this number will continue to represent the approximate size of an Arabic database.) One mechanism for achieving a

subset is to generate keys for the input name. The Arabic keys are motivated by the nature of the Arabic name and are centered around the most stable name segment in the Arabic name, the GN1.

- 2.10.3.1. The Arabic keys replace the compressed-name keys produced for Legacy ANA, which have severe limitations for retrieving both predictable and unpredictable variants of the regularized Arabic names.
- 2.10.3.2. For record adds, all keys will be stored with the source record.
- 2.10.3.3. Keys will be generated for each SN segment (moved or resident) and for each GN1.
  - 2.10.3.3.1. For record adds, more keys will be generated for HF name segments than for LF segments.
  - 2.10.3.3.2. Search keys will be a combination of SN keys and GN1 keys.

#### 2.10.4. Function

- 2.10.4.1. The AKG will form search keys from a combination of keys for each regularized segment in the Surname field and the regularized GN1.
- 2.10.4.2. Initials

All names that contain the same first character as the initial will qualify for retrieval on an initial.

#### 2.10.4.3. FNU

All GN1 names qualify for retrieval with a GN1 of FNU (First Name Unknown).

### 2.10.4.4. Search Keys

- 2.10.4.4.1. The AKG will generate a set of Search Keys for each input name by conjoining each GN1 key with each SN key of the regularized, repositioned input name.
- 2.10.4.4.2. All search keys generated for an add will be stored with the record add and associated with the regularized, repositioned form of the name.

### 2.10.4.5. Generating Keys

- 2.10.4.6. The AKG will produce two categories of keys:
  - Single-Part Key (SI): a key formed from the single name segment (SN or GN1). All Single-Part Keys will be used to form the Search Keys. There are three kinds of Single-Part Key:
    - Primary Key (PK): a key formed on a single name segment (SN or GN1) and used to define the set of keys for that segment;
    - Wild-Card Key (WK): a key based on the Primary Key that contains wild-card characters;
    - Special Key (SP): a key formed on a single name segment and intended to handle specific variation in the regularized name.

2. Search Key (SK): a multipart key that will be stored and used for retrieval, consisting of a combination of the keys associated with every SN segment and those associated with the GN1.

### 2.10.4.7. Single-Part Key (SI)

- 1. The Primary Key (PK)
  - The PK is formed from one name segment.
  - The PK has a maximum of three characters.
  - The PK has the form CCC or CC or C, where C represents any consonant (except in the leftmost position where C may be a vowel).
  - The PK is formed from the leftmost character (vowel or consonant) of the regularized segment and the following two consonants (including H, Y and W). If fewer than two additional consonants are available, then the PK may be shorter.
- 2. The Wild-Card Key (WK)
  - The WK is formed from the Primary Key.
  - The WKs will have the forms \*CC, C\*C, CC\*, where \* represents any consonant, except in the leftmost position where it may represent a vowel.
  - The WK will have the forms C\* and \*C with segments that have only two candidate characters.
  - A WK will not be formed from a Primary Key with only 1 component (i.e., C).

Figure 4: Example: Formation of Primary and Wild-Card Keys

SEGMENT	PRIMARY KEY	WIL	WILD-CARD KEYS	
GAMILA	GML	*ML	G*L	GM*
ABASI	ABS	*BS	A*S	AB*
SAID	SD	*D	S*	
DAI	D	none		<u> </u>

### 2.10.4.7.1. Special Key (SP)

- 2.10.4.7.2. The AKG will produce Special Keys (SP) to accommodate situations that cannot be accommodate by the ARR.
- 2.10.4.7.3. The AKG will generate the Special Keys in addition to the Primary and Wild-Card Keys.

### 2.10.4.7.3.1. K-Key

- 2.10.4.7.3.2. The character K alternates with null in many Arabic names, resulting in the potential overlap of many names with the K names.
- 2.10.4.7.3.3. This phenomenon is not readily handled by the ARR, so names with a K require a Special Key.

- 2.10.4.7.3.4. The K-Keys are formed in the following way:
  - 2.10.4.7.3.4.1. For any segment with K in initial position, the following keys are produced:

    \*CC where \* represents any character or nothing. (This key is equivalent to a WK produced for this name.)
  - 2.10.4.7.3.4.2. For any segment with K in medial position, the following keys are produced:
    - 1. CkC, where k represents the character "k";
    - CCC, where k has been deleted from the name string and the CCC represents the three leftmost consonants that remain; and
  - 2.10.4.7.3.4.3. For any segment with K in final position, the following keys are produced:
    - CCk, where k represents the character "k" and
    - CC, where k has been deleted from the name string and the CC represents the two leftmost consonants (or vowel in first position) that remain.
- 2.10.4.7.3.5. The standard set of Wild-Card Keys will also be produced from the Primary Key for K-names.
- 2.10.4.7.3.6. Record Add/Query: The AKG will generate and store all K-Keys with the segment.

Figure 5: Example: Formation of K-Keys

NAME SEGMENT / VARIANT	PRIMARY KEY	K - KEYS	WILD-CARD KEYS
KARSCH	KRS		*RS, K*S, KR*
ARSCH	ARS		*RS, A*S, AR*
MUKBEL	MKB	MBL	*KB, M*B, MK*
MUBEL .	MBL		*BL, M*L, MB*
FARUK	FRK	FR	*RK, F*K, FR*
FARU	FR	FR	.*R, F*

- 2.10.4.7.3.7. High Frequency Key (HK)
- 2.10.4.7.3.8. The AKG will generate Special Keys for High Frequency segments found in the input name.
- 2.10.4.7.3.9. The AKG will access the Arabic Name Type (ANT) Data Store to identify HF segments. (See Section 3.5.)

- 2.10.4.7.3.9.1. The ANT will contain a set of Arabic name types, the most frequently occurring of which will be specified as High Frequency name segments (HI\_FREQ = 1 (True)). (See Section 3.5 for details).
- 2.10.4.7.3.9.2. The AKG will tag as HF all name segments in the input record that match one of the ARABIC\_NAME\_TYPE segments for which HI\_FREQ = 1 (is True).
- 2.10.4.7.3.9.3. The AKG will tag all other name segments as LF.

### 2.10.4.7.3.10. Record Add/Query

2.10.4.7.3.11. The AKG will generate and store the Primary Key for any segment that has been tagged as a HF name segment.

### 2.10.4.7.3.12. Record Add

2.10.4.7.3.13. The AKG will generate and store all appropriate Wild-Card Keys for any segment that has been tagged as a HF name segment.

Figure 6: Example: Primary Key as HF Key

HF SEGMENT	PRIMARY KEY	WILD-CARD KEYS
MUHAMAD	МНМ	*HM, M*M, MH*
AHMED	AHM	*HM, A*M, AH*
ALI	AL	*L, A*

### 2.10.4.7.4. Search Keys (SK)

- 2.10.4.7.5. The Search Key is a multipart key formed from all keys associated with one SN segment and all keys associated with the GN1: e.g., \*CC + \*CC, \*CC + C\*C, C\*C + CC\*, etc.
- 2.10.4.7.6. The Search Keys will be the keys used for retrieval of records from the database.

### 2.10.4.7.7. Search Key Formation

- 2.10.4.7.8. To form the set of search keys that will be related to each input record, the AKG will combine each SN segment with the GN1 segment: SN1 + GN1, SN2 + GN1, etc.
- 2.10.4.7.9. The AKG will determine the frequency (HF or LF) of each of the conjoined segments.
- 2.10.4.7.10. The number and type of Search Keys will be based on the frequency of the name segments.

24

ANA-E Language Analysis Systems, Inc.

- 2.10.4.7.11. The AKG will form
  - · Standard Search Keys and
  - · HF Search Keys.
- 2.10.4.7.12. Standard Search Keys.(SS) ...
- 2.10.4.7.13. Standard Search Keys (SS) are formed for each SN and GN1 pair.
- 2.10.4.7.14. Record Add
- 2.10.4.7.15. To form a set of Standard Search Keys, the AKG will combine each Wild-Card Key and each K-Key of each SN segment with each Wild-Card Key and each K-Key of the GN1.
  - 2.10.4.7.15.1. For example, each segment with three characters (CCC) will have generated three Wild-Card Keys.
  - 2.10.4.7.15.2. When the keys from two segments with three characters each are paired, there will be a total of nine keys.
  - 2.10.4.7.15.3. For segments with fewer characters, there will be fewer than nine keys.
- 2.10.4.7.16. The AKG will generate and store these keys with the record.

Figure 7: Example: Formation of Standard Search Keys (Record Add)

REPOSITIONED, REGULARIZED INPUT FORMAT: AHMED BADAWI, MUHAMAD				
	GN1: MUHAMAD	STANDARD SEARCH KEYS		
SN1: AHMED	SNI+GNI: AHMED MUHAMAD	*HM*HM, *HMM*M, *HMMH*, A*M*HM, A*MM*M, A*MMH*, AH**HM, AH*M*M, AH*MH*		
SN2: BADAWI	SN2+GN1: BADAWI MUHAMAD	*DW*HM, *DWM*M, *DWMH*, B*W*HM, B*WM*M, B*WMH*, BD**HM, BD*M*M, BD*MH*		

- 2.10.4.7.17. Query
- 2.10.4.7.18. If either segment of the SN + GN1 pair has been tagged as LF, the AKG will generate the Standard Search Keys.
- 2.10.4.7.19. To form a set of Standard Search Keys, the AKG will combine each Wild-Card Key and K-Key of each SN segment with each Wild-Card Key and K-Key of the GN1. (See Section 2.10.4.7.15)
- 2.10.4.7.20. HF Search Keys (HS)
- 2.10.4.7.21. Query
- 2.10.4.7.22. If both segments (the, SN and the GN1) of the conjoined pair have been tagged as HF segments, the AKG will form one Search

ANA-E

- Key from the Primary Key of the SN + the Primary Key of the GN1.
- 2.10.4.7.23. The High Frequency Search Key will be the *only* Search Key used for a *query* on the SN + GN1 pair when both segments are HF segments.

### 2.10.4.7.24. Record Add

- 2.10.4.7.25. If both segments (the SN and the GN1) that have been conjoined have been tagged as HF segments, the AKG will form one Search Key from the Primary Key of the SN + the Primary Key of the GN1.
- 2.10.4.7.26. The HS will be stored with a record add.
- 2.10.4.7.27. The HS will be a key stored in addition to the Standard Search Keys for the record.

Figure 8: Example: HF Search Keys

REPOSITIO	NED, REGULARIZED INPUT FORM	AT: AHMED ALI, MUHAMAD
	GN1: MUHAMAD (HF)	HF SEARCH KEYS
	THE STATE OF THE S	АНММНМ
SINZ: ALI (HF)	SN2+GN1: ALI MUHAMAD	ALMHM

## 2.11. Retrieval Function of the Arabic Search Engine (ASE)

- 2.11.1. The Arabic Search Engine (ASE) will retrieve records from the database based on the following criteria:
- An exact match of the query Search Keys and stored Search Keys and
- Refusal Code Level and associated Year-of-Birth Range.
- 2.11.2. The ASE will access the Refusal Code Level/Year-of-Birth Range (RLYOB) Data Store to determine the YOB range within each Refusal Level to search for candidate records.
- 2.11.3. The ASE will retrieve the unique ID and the regularized, repositioned form of the record.
  - 2.11.3.1. Determination of the proximity by the Arabic Filter and Sorter of the query and database records will be based on the regularized, repositioned form of the record.
  - 2.11.3.2. The ASE will eliminate all records with the same unique ID retrieved during the retrieval process.

### 2.11.4. Subordinates

Arabic Key Generator.

ANA-E Language Analysis Systems, Inc. 26

### 2.12. ARABIC FILTER AND SORTER MODULE DECOMPOSITION (AFS).

#### 2.12.1. Identification

This module is known as the Arabic Filter and Sorter (AFS).

#### 2.12.2. Type

w.S.

- 2.12.2.1. The AFS is a module that accepts each regularized database record retrieved by the ASE and compares it to the regularized form of the query record.
- 2.12.2.2. The AFS is constituted of two subordinate functions:
  - the Arabic Filter and
  - the Arabic Sorter.
  - 2.12.2.3. The AFS must follow the Arabic Search Engine (ASE).

#### 2.12.3. Purpose

- 2.12.3.1. The set of database records that the ASE will retrieve will have no value relative to the query record. The AFS will evaluate each of the records retrieved for its proximity to a query record, will retain those that pass a pre-established threshold and will sort the resultant candidate list.
- 2.12.3.2. The filtering process will take into account a number of factors that play a role in determining the relative value of Arabic names.

### 2.12.4. Function

2.12.4.1. The AFS will compare the query name and record name to determine a relative surname value and given name value and will generate a composite score for the records by accounting for Date-of-Birth, Refusal Level and Country-of-Birth proximity.

### 2.12.4.2. Arabic Filter Function of the AFS

- 2.12.4.3. The Arabic Filter and Sorter will first determine if the query record and prime database record (unregularized version) match exactly.
  - 2.12.4.3.1. The Surname, Given Name, Date-of-Birth and Country-of-Birth must be exact matches.
  - 2.12.4.3.2. If the two records match exactly, the AFS will tag the record as an exact match.
  - 2.12.4.3.3. The AFS will send the record directly to the Arabic Sorter Function.

- 2.12.4.4. The Arabic Filter and Sorter (AFS) will accept the regularized, repositioned candidate records retrieved by the ASE.
- 2.12.4.5. The AFS will perform a digraph comparison of the regularized, repositioned surname segments (stems) of the query record and each candidate record.
- 2.12.4.6. The AFS will perform a digraph comparison of the regularized given name segment (stem) of the query record (GN1) and the given name segment (stem) of each candidate record (GN1).
  - 2.12.4.6.1. The score produced by the digraph comparison (DI\_VAL) will be adjusted by values assigned to several parameters.
  - 2.12.4.6.2. The score assigned to the surname and to the given name, after the parameters have adjusted the DI\_VAL, will be the SN\_VAL and the GN\_VAL.
  - 2.12.4.6.3. Factors that contribute to the determination of the name scores (SN VAL and GN VAL) include
    - SNTHR
    - GNTHR
    - OPVAL
    - INITSN
    - INITGN
    - TAQASN
    - TAQAGN
    - TAQXSN
    - TAQXGNGNDR
  - 2.12.4.6.4. A final name score will be calculated for each candidate database record as it compares to the query record.
    - 2.12.4.6.4.1. A score for the SN will be calculated: SN\_VAL.
    - 2.12.4.6.4.2. A score for the GN will be calculated: GN\_VAL.
  - 2.12.4.6.5. To be included in the final candidate list, the SN\_VAL and GN\_VAL must each pass pre-determined SN and GN threshold levels (SNTHR and GNTHR).
- 2.12.4.7. Surname Evaluation
- 2.12.4.8. The AFS will perform a digraph comparison of each SN stem of the database record with each SN stem of the query record.
  - 2.12.4.8.1. The digraph value is determined in the following way:
    - 2.12.4.8.1.1. The digraphs are identified for each name stem.
      - 2.12.4.8.1.1.1. Each pair of alphabetic characters is identified: TAFIQ → TA/AF/FI/IQ

- 2.12.4.8.1.1.2. A digraph is also formed of the initial boundary (#) and the first alphabetic character:

  TAFIQ → #T.
- 2.12.4.8.1.1.3. A digraph is also formed of the final alphabetic character and the final boundary (#):

  TAFIQ → Q#.
- 2.12.4.8.1.2. The number of shared digraphs is calculated.
  - 2.12.4.8.1.2.1. A digraph may match one digraph only.
- 2.12.4.8.1.3. The number of shared digraphs is multiplied by 2 and divided by the total number of digraphs in Comparand #1 added to the total number of digraphs in Comparand #2.
  - 2.12.4.8.1.3.1. The formula is:

2 \* d / a + b, where d = the total number of shared digraphs; where a = the total number of digraphs in Comparand #1; and where b = the total number of digraphs in Comparand #2.

2.12.4.8.1.4. The result is the Digraph Value (DI\_VAL) for the two Comparands.

Figure 9: Example: Digraph Calculation

COMPARANDS	DIGRAPHS	SHARED DIGRAPHS	DI_VAL
COMPARAND #1: BADIR	#B BA AD DI IR R# (6 total digraphs = a)	BA AD DI IR R#	2*d/a+b= 10/13
COMPARAND #2: ABADIR	#A AB BA AD DI IR R# (7 total digraphs = b)	= 5 (d)	0.77

- 2.12.4.9. This process is performed for each of pair of Comparands in the database and query SN (SN1/SN1, SN1/SN2, SN1/SN3, SN2/SN2, etc.).
- 2.12.4.10. Each DI\_VAL is adjusted according to parameter values in the Filter Parameter Data Store (see Section 3.6 for details).
- 2.12.4.11. The AFS will determine if the appropriate parameter conditions are met
- 2.12.4.12. If the appropriate conditions are present, the DI\_VAL will be multiplied by the value assigned to the parameter and the relative score of the two Comparands will be lowered.

#### 2.12.4.13. Parameter Conditions

د د ادفقه

- 2.12.4.13.1. INITSN: Surname Initial
  - 2.12.4.13.1.1. Definition: A SN segment is a single character and it matches the first character of the other comparand.
  - 2.12.4.13.1.2. Action: Assign the INITSN value to the comparison value (i.e., do not calculate the DI\_VAL).
- 2.12.4.13.2. OPSN: Out-of-Place Surname
  - 2.12.4.13.2.1. Definition: A SN segment that is not in the same relative position in the SN string in both the database and query records.
  - 2.12.4.13.2.2. Action: Multiply the DI\_VAL by the OPSN value. (See Figures 10 and 11.)
- 2.12.4.13.3. TAQ Filter
- 2.12.4.13.4. All TAQ tags (ID\_NO, disposition, TAQ\_TYPE and associated SN stem) will be retrieved with the database record.
- 2.12.4.13.5. The AFS will evaluate any TAQs associated with the SN segments being evaluated, except Stranded Affixes (see Section 2.5.4.2.7.3).
  - 2.12.4.13.5.1. A Stranded Affix will not play a role in the prefix comparison.
- 2.12.4.13.6. Single TAQs
- 2.12.4.13.7. Missing TAQs
- 2.12.4.13.8. TAQASN: Absent TAQ Value
  - 2.12.4.13.8.1. Definition 1: One of the two comparands has a TAQ tag, the other does not.
  - 2.12.4.13.8.2. Definition 2: Both SN segments have a single TAQ tag, one is a TAQ DELETE, the other a TAQ DISREGARD.

ANA-E Language Analysis Systems, Inc. 30

2.12.4.13.8.3. Action: Multiply the DI\_VAL by the TAQASN value. (See Figures 12 and 22.)

#### 2.12.4.13.9. TAQ DELETE

و المافقية

- 2.12.4.13.9.1. If the TAQ DELETE tags refer to the same TAQ segment, the DI VAL will be unchanged.
- 2.12.4.13.9.2. If the TAQ DELETE tags refer to different TAQ DELETE segments, multiply the DI\_VAL by the TAQXSN value. (See Figure 22.)

### 2.12.4.13.10. TAQ DISREGARD Processing

- 2.12.4.13.10.1. The AFS will access the TAQ Filter Data Store (TF) to process SN TAQ segments that have been tagged as DISREGARD.
- 2.12.4.13.10.2. Definition: The AFS will access the TAQ Filter
  Data Store (TF) to process records if they both contain
  SN TAQ segments that have been tagged as
  DISREGARD.
- 2.12.4.13.10.3. Action 1: The AFS will assign TAQDIS#1 to the TAQ DISREGARD segment for the database SN segment and TAQDIS#2 to the TAQ DISREGARD segment for the query SN segment.
- 2.12.4.13.10.4. Action 2: If the two TAQ DISREGARD segments match, the DI\_VAL will remain unchanged.
- 2.12.4.13.10.5. Action 3: If the two TAQ DISREGARD segments do not match, the AFS will identify the TF\_VALUE for the pair in the TF. (See Figure 24.)
  - 2.12.4.13.10.5.1. The AFS will multiply the DI\_VAL by the TF\_VALUE for the pair.

### 2.12.4.13.11. Multipart TAQs

- 2.12.4.13.11.1. Definition: If at least one SN comparand has multipart TAQ tags (they may be all DISREGARD, all DELETE, or mixed DISREGARD/DELETE), the AFS will perform the following analyses.
- 2.12.4.13.11.2. Action: If all TAQs match, AFS will make no change in the DI\_VAL.

### 2.12.4.13.11.3. TAQ DELETEs

- 2.12.4.13.11.3.1. Definition: All DELETE tags
- 2.12.4.13.11.3.2. Action 1: If any DELETE TAQ matches, the AFS applies no change.

2.12.4.13.11.3.3. Action 2: If no DELETE TAQs match, multiply the DI\_VAL by the TAQXSN Value.

### 2.12.4.13.11.4. TAQ DISREGARDs

- 2.12.4.13.11.4.1. Definition: All DISREGARD tags
- 2.12.4.13.11.4.2. Action 1: If any TAQ DISREGARD segment matches, the AFS will make no . change in the DI VAL.
- 2.12.4.13.11.4.3. Action 2: If no TAQ DISREGARD segments match, the AFS will identify the highest match value from the TF (TF\_VALUE) and multiply that by the DI\_VAL. (See Figures 23 and 24.)

### 2.12.4.13.11.5. TAQ DISREGARD and DELETEs

- 2.12.4.13.11.5.1. Definition: Mixed DISREGARD/DELETE tags
- 2.12.4.13.11.5.2. Action 1: If DISREGARD segments are present in both comparands and there is any match among the DISREGARD segments, the AFS will make no change in the DI VAL.
- 2.12.4.13.11.5.3. Action 2: If DISREGARD segments are present in both comparands and there is no match among the DISREGARD segments, the AFS will determine the highest match value from the TF for any DISREGARD tags and multiply the DI\_VAL by that value. (That is, ignore any DELETE tags.)
- 2.12.4.13.11.5.4. Action 3: If a DISREGARD segment is in one comparand and not the other and the two comparands have at least one DELETE tag that matches, the AFS will make no change in the DI\_VAL.
- 2.12.4.13.11.5.5. Action 4: If a DISREGARD segment is in one comparand and not the other and the two comparands have DELETE tags that do not match, multiply the DI\_VAL by the TAQXSN. (See Figure 22.)
- 2.12.4.14. After all evaluations have been performed, the AFS will choose the highest score for each name segment.
  - 2.12.4.14.1. The highest score for both the row and column must be chosen.

ANA-E Language Analysis Systems, Inc.

. 32

2.12.4.14.2. Only one score per row and column is permitted.

2.12.4.14.3. If two scores are equal, only one is chosen.

Figure 10: Example 1: Digraph Evaluation: Equal Number of SN Segments; Digraph Variants BADAWI/BEDAWI

	AHMED	ALI	BADAWI
AHMED	1.00	0.20	0.00
ALI	0.20	1.00	0.18
BEDAWI	0.15	0.18	0.71

Figure 11: Example 2: Digraph Evaluation: Different Number of SN Segments; OPSN applies to BADAWI/BEDAWI

	AHMED	ALI	BADAWI
AHMED	1.00	0.20	0.00
BEDAWI	0.15	0.18	0.61

Figure 12: Example 3: Digraph Evaluation: Same Number of SN Segments; TAQ Tag Present on One SN

4111600	(ABU) AHMED	SALIM	SAYED
AHMED	0.90	0.00	0.28
SAID	0.00	0.36	0.47
AKBAR	0.16	0.00	0.00

Figure 13: Example 4: Digraph Evaluation: Same Number of SN Segments; Different TAQ\_DISREGARD Segments Present

(DIN) ATTACED	(ABU) AHMED	SALIM	SAYED
(BIN) AHMED	0.50	0.00	0.28
SAID	0.00	0.36	0.47
AKBAR	0.16	0.00	0.00

2.12.4.15. The AFS will sum the values chosen from the comparison matrix and will divide by the number of values chosen to produce the SN\_VAL.

2.12.4.15.1. In Example 1, 1.00 + 1.00 + 0.61/3 = 0.87

2.12.4.15.2. In Example 2, 1.00 + 0.61/2 = 0.81

2.12.4.15.3. In Example 3, 0.90 + 0.47 + 0.00/3 = 0.46

2.12.4.15.4. In Example 4, 0.50 + 0.47 + 0.00/3 = 0.32

2.12.4.16. The AFS will compare the SN\_VAL to the SNTHR.

2.12.4.16.1. The SN\_VAL must be equal to or greater than the SNTHR.

2.12.4.16.2. The record must pass the SNTHR to qualify for the final candidate list.

## 2.12.4.17. Given Name Evaluation

- 2.12.4.18. The GN has only one segment, the GN1.
  - 2.12.4.18.1. The AFS will perform a digraph comparison on the regularized GN1 stem of the database record and the regularized GN1 of the query record.
  - 2.12.4.18.2. The DI\_VAL will be calculated as it was for the SN (see Section 2.12.4.8).
  - 2.12.4.18.3. The DI\_VAL will be adjusted by several GN parameters.
  - 2.12.4.18.4. INITGN: Given Name Initial
    - 2.12.4.18.4.1. Definition: A GN1 is a single character and matches the first character of the GN1 of the other comparand.
    - 2.12.4.18.4.2. Action: Assign the INITGN value to the comparison value (i.e., do not calculate a DI\_VAL)
  - 2.12.4.18.5. TAQ Evaluation will proceed as with the SN, mutatis mutandi (see Section 2.12.4.13.3).
  - 2.12.4.18.6. GNDR: Record Gender Value
    - 2.12.4.18.6.1. The AFS will compare the record gender of the input name and the query name.
    - 2.12.4.18.6.2. If the genders match, no action will take place.
    - 2.12.4.18.6.3. If the genders do *not* match, multiply the DI\_VAL of the GN1 by the GNDR value. (See Figure 24.)
- 2.12.4.19. The value resulting from all GN1 calculations will be the GN\_VAL.
- 2.12.4.20. The AFS will compare the GN\_VAL to the GNTHR. (See Figure 24.)
  - 2.12.4.20.1. The GN\_VAL must be equal to or greater than the GNTHR.
  - 2.12.4.20.2. The record must pass the GNTHR to qualify for the final candidate list.

- 2.12.4.21. Composite Score
- 2.12.4.22. The AFS will develop a Composite Score for the two comparands.
- 2.12.4.23. The AFS will adjust the GN\_VAL and the SN\_VAL by factors that reflect the proximity of the Refusal Level, Date of Birth and Country of Birth.
- 2.12.4.24. The GN\_VAL and SN\_VAL will be multiplied by factors that apply to the RL, DOB and COB.
- 2.12.4.25. Refusal Level Factor
- 2.12.4.26. The AFS will access the Refusal Code Level Data Store to determine the Refusal Level Category of the Refusal Code.
- 2.12.4.27. The AFS will access the Filter Parameter Data Store to find the PARM\_VAL associated with the Refusal Level (RL#).
- 2.12.4.28. Date-of-Birth Factor
- 2.12.4.29. The AFS will access the Year-of-Birth Range Data Store to determine the YOB Category, YOB#, of the Dates-of-Birth of the comparands. The highest value is applied to the relationship.
- 2.12.4.30. The AFS will access the Filter Parameter Data Store to find the PARM\_VAL associated with the YOB Category (YOB#).
- 2.12.4.31. Country-of-Birth Factor
- 2.12.4.32. The AFS will access the Country of Birth Category Data Store to determine the COB Category, COB#.
- 2.12.4.33. The AFS will access the Filter Parameter Data Store to find the PARM\_VAL associated with the Country of Birth Category (COB#).
- 2.12.4.34. The AFS will calculate a composite score by multiplying the SN\_VAL by the GN\_VAL by the RL# PARM\_VAL by the YOB# PARM\_VAL by the COB# PARM\_VAL.
- 2.12.4.35. Final Sort Function of the AFS
- 2.12.4.36. The AFS will rank order the final candidate list of database records.
- 2.12.4.37. The prime (unregularized) record will be returned to the user.
  - 2.12.4.37.1. There may be significant differences between the query record and the qualifying database records.
  - 2.12.4.37.2. The Composite Score will be returned with the record.

- 2.12.4.38. Any record that is tagged as an exact match will be placed at the top of the list.
- 2.12.4.39. All remaining records in descending order of Composite Score.
- 2.12.4.40. The goal of the final sort is to place exact record matches on the top and to rank order the remaining records by the degree of contribution that each data element (SN, GN, DOB, COB, Refusal Code Level (RL)) makes to the overall record value.
- 2.12.4.41. The details of the sort will be derived from extensive discussion about the business requirements.
- 2.12.4.42. Because the scores from the various pipes may not have been calculated in the same way, a method for evaluating the relative value of candidate records will have to be devised.

#### 2.12.4.43. Internal Order

- 2.12.4.43.1. There may be cases in which the sorting criteria are met equally by more than 1 record.
- 2.12.4.43.2. Where multiple records qualify equally, there will be an internal sort order.
  - 2.12.4.43.2.1. SN Score
  - 2.12.4.43.2.2. GN Score
  - 2.12.4.43.2.3. DOB Levels
  - 2.12.4.43.2.4. Refusal Levels
  - 2.12.4.43.2.5. COB Relationships
- 2.12.4.44. The AFS will return the top n records to the central CLASS-E sorter.
  - 2.12.4.44.1. The number of records to be returned will be a system setting.

### 2.13. LINGUISTIC TRACE FACILITY MODULE DECOMPOSITION

### 2.13.1. Identification

This module is known as the Linguistic Trace Facility (LTF).

#### 2.13.2. Type

The LTF is a program that will interact with any or all modules and functions within those modules.

### 2.13.3. Purpose

The LTF will allow system evaluators to access information about the system functions so that the quality of the content can be ensured. To diagnose and remedy problems associated with questionable system results, evaluators must

have access to the results of system functionality at various points during the processing cycle.

#### 2.13.4. Function

ر اینافشد

17.15

- 2.13.4.1. The LTF will be a mechanism that will copy and divert statistics, information, processing results to a file outside the main processing module.
- 2.13.4.2. The file will be readily accessible on-line for examining by a system evaluator.
- 2.13.4.3. Multiple trace points will be identified when the system is built.
- 2.13.4.4. Examples of trace points:
  - What ARRs (by ID NO) have applied
  - Regularized, repositioned name form
  - All keys generated for a query and for an add
  - SN and GN DI\_VAL
  - SN\_VAL and GN\_VAL
  - Record Gender
  - Sort considerations

#### DATA DECOMPOSITION

### 3.1. DATA

- 3.1.1. The input data for an ANA-E query will contain all information that is currently required by CLASS and in the standard format required by CLASS.
  - NAME (Surname, Given Name);
  - DOB (Date of Birth; Day Month Year); and
  - COB (Country of Birth; FIPS codes).

In addition, the following will be specified:

- Applicant Gender (AG): Male (M), Female (F), Unknown (U).
- A unique identifier (UID) (as defined in CLASS-E).
- 3.1.2. For adds, other record information will be entered, as required by CLASS and CLASS-E: e.g., refusal code, province of birth.

### 3.2. DATA STORES

The following data stores will be accessed by the ANA-E processing components:

- Arabic Regularization Rules Data Store (ARR)
- Arabic Title/Affix/Qualifier Data Store (ATD)
- Arabic Name Type Data Store (ANT)
- Filter Parameter Data Store (FP)
- TAQ Filter Data Store (TF)
- Refusal Code Level Data Store (RCL)

- YOB Range Data Store (YR)
- Refusal Code Level/Year-of-Birth Range Data Store (RLYOB)
- COBPROX Data Store (COBPROX)
- Arabic COB Category Data Store (ACOB)

### 3.3. ARABIC REGULARIZATION RULES DATA STORE DECOMPOSITION

#### 3.3.1. Identification

This rule base is known as the Arabic Regularization Rule Base (ARR).

### 3.3.2. Type

يتعانيه

- 3.3.2.1. The ARR is a set of transformation rules accessed by the Arabic Rule Engine.
  - 3.3.2.2. The ARR will have the following format:

Figure 14: Format: Arabic Regularization Rule Base

FIELD NAME	DATA TYPE	FIELD SIZE	DATA VALUE
ID_NO	integer	3	001999
PRE-CONTEXT	character	unlimited	any ASCII character
IN	character	unlimited	any ASCII character
POST-CONTEXT	character	unlimited	any ASCII character
OUT	character	unlimited	any ASCII character

### 3.3.2.3. Definitions

- 3.3.2.3.1. ID\_NO: a unique, arbitrary numerical reference to the rule.
- 3.3.2.3.2. PRE-CONTEXT: preceding context for the element to be matched; delimited by preceding and following quotation marks ("")
- 3.3.2.3.3. IN: the match context; the portion of the name that will undergo change; delimited by preceding and following quotation marks ("")
- 3.3.2.3.4. POST-CONTEXT: trailing context for the element to be matched; delimited by preceding and following quotation marks ("")
- 3.3.2.3.5. OUT: the rule output; the realized change in the IN; delimited by preceding and following quotation marks ("")

- 3.3.2.4. There is no internal limit on the size of the Pre-Context, In, Post-Context or Out, although the system may have an external limit (e.g., the maximum size of the SN field).
- 3.3.2.5. All rules will use standard regular expression notation, with one exception (\$), which has been defined specifically for this rule base.

### 3.3.2.6. Regular Expression Notation

Figure 15: Regular Expression Notation

REGEXP NOTATION	DEFINITION	
ŧ.	Matches any single character, including white space.	
-	Stands for all characters that come between the two characters given. This is a standard "fromto" notation; with characters, it presumes an A to Z character set. For example, [A-D] will match on A or B or C or D. (See [] below.)	
[]	Identifies a class of characters; a match can occur on a single occurrence of any single element within the []: [OU] will match O or U. For example, "J[OU]N" will match on JON or JUN but not on JOUN. If a + is added to the bracketed expression, "J[OU]+N", it will match on any combination of any number of Os and Us: JOUUN, JUUON, JOUOUN, JUUN, JOUUN, etc. In contrast, OU without [] will match only on the exact combination of characters OU: "JOUN" will match on JOUN only.	
+	Matches one or more occurrences of a preceding character or regular expression, in any order.  For example, JO+N will match JON or JOON or JOOON, etc., [OU]+ matches OOOU or OUOUOU or O or UO or OOU or UUUO, etc.	
?	Matches zero or <i>one</i> occurrence of the preceding regular expression. The expression "JOH?N" will match on JON or JOHN but will not match on JOHHN.	
•	Matches zero or more occurrences of the preceding regular expression. The expression "JOH*N" will match on JON, JOHN, JOHHN, JOHHHHN, etc.	
()	Groups together regular expressions. "(J[OU]N H[AE]RRY)" will match on JON or JUN or HARRY or HERRY. (Contrast with [] which identifies a character class and contrast with {} which identifies a metasymbol.)	
1→(1)	Matches either the preceding regular expression or the following regular expression. The full expression is all contained within (). For example, (AB AP) will match the character string AB or AP. The same expression may also be written A[BP].	
4.11	Defines the context boundary: the Preceding Context, Match Context, Post Context and Output. A context that is made up of only one metasymbol and is not bracketed by {·} should not be surrounded by "". For example, the metasymbol Consonant can stand alone. If the metasymbol is enclosed within {}, then all regular expressions contained within the context must be enclosed within "". For example, "{Consonant} {Letter}" within one context requires both {} and "".	
. ()	Contains one or more pre-defined metasymbols. If { } are used, they must be surrounded by "". If a single metasymbol occurs alone, no { } are necessary and therefore no "" are necessary. For example, the single metasymbol Vowel can appear either as Vowel or "{Vowel}". If more than one element is used, the metasymbol must all appear within { } and the whole string within "". E.g., Vowel, "{Vowel}", "J{Vowel}HN" are acceptable formats.	
\$	Indicates the character to output. \$ is defined differently from other standard definitions. \$ is a variable that is followed by an integer that references a character in the match string. For example, each character in an input string is associated with a different, consecutive integer value, up to the number of characters in the match: JONES becomes J = \$1, O = \$2, N = \$3, E = \$4, S = \$5. Reference can be made to the index values in the output string. \$1 \$2 \$2 \$3 \$3 \$5 would represent JOONNS.	

### 3.3.2.7. Metasymbols

A number of meta-symbols will be accessed by the rules. The metasymbols are variables declared at the beginning of the ARR Data Store.

Figure 16: ARR Metasymbols

nadisi.

METASYMBOL	DEFINITION
Letter	"[A-Z]"
Consonant	"[BCDFGHJKLMNPQRSTVWXYZ]" (N.B. Includes W and Y)
Nog (= No Glide)	"[BCDFGHJKLMNPQRSTXZ]" (N.B. No W or Y)
Alla	"[AEOUI]+L+[EA]+H?"
Rhyme	"[AEIOUY]+[BCDFGHJKLMNPQRSTVWXYZ]"
Kesra	"([EA]?[IY]+ [IE]+ Y)"
Dad	"(Z+ TH+ DH+ DD+)"
Tha	"(Z+ TH+ DH+ C+ S+ T+)"
Jim	"(DJ J Y G DZH DSCH GG DY)"
Gine	"(G GH RH)"
Qaf	"(Q G K J KH GH C QU CK)"
Kha	"(KH K X Q C)"
Marbuta	"([EAI]H [AE]T?)"
Sun	"(C S N D T R Z G J)"
Sungem	"(SS NN DD TT RR ZZ GG JJ)"
Moongem	"(BB FF GG HH JJ KK MM NN PP QQ VV WW XX)"
Vowelgem	"(AA EE II OO UU)"
Vowel	"[AEIOU]"
Didi	"(KHKH SHSH GHGH RHRH DHDH THTH CHCH PHPH)"
Dig	"[KSGRDTCP]H"
Bound	" " (= white space)
Anything	11 11
Othergem	"(CC LL YY)"

### 3.3.2.8. Purpose

The ARR allow records with highly divergent spellings and/or representations of the same name to be retrieved from the database. Usual character comparison techniques are unable to retrieve records with these variants.

#### 3.3.2.9. Function .

The ARR applies relevant rules to each Arabic name field and produces a common representation for variant realizations of the same name.

MUHAMMED, MOHAMMAD and IMHEMED are variant forms of the same name; each will be set equal to one single representation of the name: MUHAMAD, for example. The successful application of one or more rules will produce as output a regularized Arabic name string.

### 3.3.2.10. Examples

3.3.2.10.1. Example 1 contains two rules that apply to variants of ABDULLA:

ANA-E Language Analysis Systems, Inc. 40

- EVDILLAH
- ABD ALA
- ABDU ALLA
- ABDULLAH
- OABDELA
- AABDILA
- ABDELILA

Figure 17: Example 1: "ABDULLA" Regularization Rules

40.76

۱.	ID NO	PRE- CONTEXT	IN (MATCH CONTEXT)	POST- CONTEXT	OUT
- 1	.676	Bound	"[HKCQ]?[AE]+[BV]*D+{Vowel}?{Bound}{Alla}"	Bound	"abdula"
	677	Bound	"[HKCQ]?[AE]+[BV]*D+[AEIOU]*L+[IE]*L*AH?"	Bound	"abdula"

3.3.2.10.2. Example 2 contains one rule that applies to variants of G:

- MAGUID
- MADZHID
- MADSCHID
- MADJID
- МАЛО
- GHASSAN

Figure 18: Example 2: "G" Regularization Rules

	ID NO	PRE- CONTEXT	IN (MATCH CONTEXT)	POST-CONTEXT	OUT
T	132	Anything	"(DJ GH DSCH DZH J+)"	Anything	"g"

### 3.4. · ARABIC TITLE/AFFIX/QUALIFIER DATA STORE DECOMPOSITION

Because the ANA-E design is viewed as an independent sub-program of the CLASS-E system, the Arabic Title/Affix/Qualifier Data Store is presented here as a separate table. It is strongly suggested, however, that CLASS-E support one TAQ Data Store in which the cultural affinity of each TAQ segment is indicated. This is reduce table maintenance and will provide a global picture of the handling of TAQs.

### 3.4.1. Identification

This data store is known as the Arabic Title/Affix/Qualifier Data Store (ATD).

### 3.4.2. **Type**

The ATD is a data store that contains the Arabic-specific Title, Affix and Qualifier segments and their distribution. It will be accessed by the Arabic Preprocessor (APP) and the Arabic Filter and Sorter.

Figure 19: Format: Arabic TAQ Data Store

DATA FIELD	DATA TYPE	FIELD SIZE	DATA VALUE
ID_NO	integer	4	19999
TAQ FORM	character	15	alphabetics
TAQ TYPE	character	1	T, P, I, S, Q
DELETE	integer	1	1, 0 (True, False)
DISREGARD	integer	1	1, 0 (True, False)

#### 3.4.2.1. Definitions

- 3.4.2.1.1. ID\_NO: a unique, arbitrary number that identifies the TAQ segment.
- 3.4.2.1.2. TAQ FORM: the string that represents the TAQ; the TAQ FORM may be a multipart string (i.e., a string that includes internal white space).
- 3.4.2.1.3. TAQ TYPE: an indicator of the kind of TAQ segment present: a title (T), prefix (P), infix (I), suffix (S) or qualifier (Q).

### 3.4.2.1.4. DELETE:

- 3.4.2.1.4.1. The segment is to be removed from all further consideration in the name search process; it will contribute marginally to the filtering process. It will be returned with the record to the user.
  - 3.4.2.1.4.2. The segment is referenced in the filtering process.
  - 3.4.2.1.4.3. The segment is not removed from the original record and is returned with the record to the user.
- 3.4.2.1.4.4. True (1) or False (0) indicates whether or not this function is to apply to the segment(s) under consideration.

### 3.4.2.1.5. DISREGARD:

- 3.4.2.1.5.1. The segment is to be removed from further consideration in the name search process but will undergo special evaluation in the filtering process. It will be returned with the record to the user.
- 3.4.2.1.5.2.True (1) or False (0) indicates whether or not this function is to apply to the segment(s) under consideration.

### 3.4.3. Purpose

Peripheral elements (Titles, Affixes, and Qualifiers) in names do not contribute as much to the name evaluation as does the name stem. Identifying and

removing these elements in the name processing component is important. They do, however, contribute to the overall value of a name when compared to another name. They will therefore contribute some value to the filtering and sorting processes.

### 3.4.4. Function

The ATD serves as a repository for all TAQ values and for the treatment that each will be subjected to.

### 3.5. ARABIC NAME TYPE DATA STORE DECOMPOSITION

### 3.5.1. Identification

This data store is known as the Arabic Name Type Data Store (ANT).

### 3.5.2. Type

\*(\*),(\*)

- 3.5.2.1. The ANT is a data store of unique regularized Arabic name segments.
- 3.5.2.2. The ANT is generated only after regularization has applied to the input name.
- 3.5.2.3. The ANT will have the following format:

Figure 20: Format: Arabic Name Type Data Store

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE
ID_NO	integer	5	0000199999
ARABIC_NAME_TYPE	character	24	alphabetics
GENDER	character	1	M, F, U
HI_FREQ	integer	1	1, 0 (True or False)

- 3.5.2.4. Definitions
- 3.5.2.5. ID\_NO: a unique, arbitrary numerical reference to the name segment (ARABIC NAME\_TYPE)
- 3.5.2.6. ARABIC\_NAME\_TYPE: unique entries that correspond to the *regularized* form of a name segment.
- 3.5.2.7. GENDER: the gender associated with a particular name segment: M (Male), F (Female), U (Unknown/Unspecified). As records are added to the ANT, gender will be specified as U. The gender assigned to new table entries will be periodically reevaluated so that names that can be identified for gender can be appropriately marked.
- 3.5.2.8. HI\_FREQ: the frequency of all names will be indicated. True (1) will indicate that a name segment is considered a high frequency Arabic name segment. All other segments will be marked as False (0), a low-frequency name segment.

#### 3.5.3. Purpose

The purpose of the ANT data store is to reduce the need to perform repeated digraph comparisons on a large store of names and to permit the retrieval of gender-matching records.

## 3.5.4. Function

The ANT will provide information about the distinct Arabic name types, their frequency and gender.

#### 3.6. FILTER PARAMETER DATA STORE DECOMPOSITION

#### 3.6.1. Identification

This module is known as the Filter Parameter Data Store (FP).

#### 3.6.2. Type

- 3.6.2.1. The FP is a data store that will be accessed by the Filter Component of the Arabic Filter and Sorter (AFS).
- 3.6.2.2. The FP is a parameter table that will be accessible to and adjustable by the user and whose cell values will be determined through testing and comparative evaluation.
- 3.6.2.3. The FP has the following format:

Figure 21: Format: Filter Parameter Data Store

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE	DATA VALUE
PARM NAME	character	6	alphabetics	SNTHR, GNTHR,
_	'			OPSN, INITSN,
				GNDR, INITGN,
	1		•	TAQASN, TAQAGN,
				TAQXSN, TAQXGN,

		RL#, YOB#, COB#
	4 0.001.99	Various (TBD)
PARM_VAL decimal		

Figure 22: Example: Filter Parameter Data Store (Values are for example only.)

Figure 22: Exam	ipie: Filler Farameter
PARM_NAME	PARM_VAL
SNTHR	0.60
GNTHR	0.65
OPSN	0.60
INITSN	0.85
INITGN	0.85
GNDR	0.65
TAQASN	0.90
TAQAGN	0.90
TAQXSN	0.85
TAQXGN	0.85
RL0	1.20
RLI	1.15
RL2	1.10
RL3	1.05
RL4	1.00
YOB0	1.30
YOBI	1.25
YOB2	1.20
YOB3	1.15
YOB4	1.10
YOB5	1.05
YOB6	1.00
COBI	1.20
COB2	1.15
COB3	1.10
COB4	1.00
COB5	0.95

wite,

3.6.2.4. The values provided are as examples only and do not necessarily represent the PARM\_VALs to be used for the parameters.

# 3.6.3. Purpose

The FP is a data store that allows easy access to adjustable parameters that contribute to the determination of the composite score of two record comparands.

# 3.6.4. Function

The FP functions as an independent data store with all the adjustable parameters needed by the AFS during the filtering process.

# TAQ FILTER DATA STORE DECOMPOSITION

# 3.7.1. Identification

This data store is known as the TAQ Filter Data Store (TF).

## 3.7.2. Type

- 3.7.2.1. This TF will be accessed by the Arabic Filter and Sorter and provides parameter factors for matching TAQ DISREGARD tags during record filtering.
- 3.7.2.2. The format of the TF follows:

Figure 23: Format: TF Matrix Design

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE	DATA VALUE
TAQDIS#1	character	8	alphabetics	TAQ_DISREGARD ITEM
TAQDIS#2	character	8	alphabetics	TAQ_DISREGARD ITEM
TF VALUE	decimal	-4	0.001.00	Various (TBD)

#### 3.7.2.3. Definitions

- 3.7.2.4. TAQDIS#1: is the TAQ DISREGARD segment that occurs in one or the other (different) of the comparands.
- 3.7.2.5. TAQDIS#2: is the TAQ DISREGARD segment that occurs in one or the other (different) of the comparands.
- 3.7.2.6. TF\_VALUE: is the factor that will be used to adjust the SN\_VAL or GN\_VAL if the TAQDIS#1 and TAQDIS#2 are present in the comparands.

Figure 24: Example: TF Sample (Values are for example only)

TAQDIS#1	TAQDIS#2	TF_VALUE
ABD EL	ABD EL	1.00
ABD EL	ABU	0.75
ABD EL	AL	0.85
ABD EL	BIN	0.75
ABD EL	EL DIN	0.50
ABU	ABU	1.00
ABU	AL	0.85
ABU	BIN -	0.50
ABU	EL DIN	0.85
AL	AL	1.00
AL	BIN	0.85
AL	EL DIN	0.50
BIN	BIN	1.00
BIN	EL DIN	0.85
EL DIN	EL DIN	1.00

#### 3.7.3. Purpose

Arabic names often have peripheral name elements. Some of these make up a segment of the name, the TAQ values identified in the TF. Their relative value, however, varies. Some of them cannot cooccur, some have opposite

meanings, so it is necessary to identify their relative value when they are contrasted with one another.

#### 3.7.4. Function

The TF provides the resources for the AFS to determine the relative value of two TAQs that occur in two comparands.

#### 3.8. REFUSAL-CODE LEVEL DATA STORE DECOMPOSITION

#### 3.8.1. Identification

This data store is known as the Refusal Code Level Data Store (RCL).

#### 3.8.2. Type

- 3.8.2.1. It is recommended that the RCL be a parameter file, which can be accessed by the client so RC categories can be added to or changed with ease.
- 3.8.2.2. The RC data store will provide a list of the Refusal Codes and the level of seriousness of each Refusal Code.
- 3.8.2.3. The RCL has the following format:

Figure 25: Format: Piece of Refusal Code Level Data Store (RCL)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE	CATEGORY DEFINITION
00	alphanumerics	3	RL0	Most serious RC: 00
23	alphanumerics	3	RLI	Type 1 Serious RCs
6C	alphanumerics	3	RL2	Type 2 Serious RCs
07	alphanumerics	3	RL3	Type I Non-serious RCs
G	alphanumerics	3	RL4	Type 2 Non-serious RCs

## 3.8.2.4. Definitions

- 3.8.2.4.1. DATA FIELD: indicates each Visa Refusal Code (Codes and their Refusal Level (see VALUE) are for example only; they do not represent the complete list nor the accurate assignment of a Refusal Code to a Refusal Level).
- 3.8.2.4.2. DATA TYPE: The RL# will appear in the form RL1, RL2, etc.
- 3.8.2.4.3. VALUE: RL# is the Refusal Level category to which are particular Refusal Code has been assigned. The Visa Office will assign Refusal Codes to one of 4 categories: RL1, RL2, RL3, RL4, RL0 is reserved for the Refusal Code 00. (The current distinction among Refusal Codes is a binary one: serious and non-serious. Assignment of Refusal Codes to more groups has not yet been done; the consequence is that one or more of these categories may not have a distinct value.) The RL# occurs in

ascending order, from most serious to least serious Refusal Code. The RL# will be linked to a Year-of-Birth Code (see Section 3.9) to determine the relevant subsets of records to be searched.

## 3.8.2.4.4. CATEGORY DEFINITION:

- RC0 refers to the Refusal Code 00.
- RC1 refers to all Refusal Codes that have been designated as Type 1 Serious RC 1, i.e., the most serious, excluding 00.
- RC2 refers to all Refusal Codes that have been designated as Type 2 Serious RC, i.e., serious but less serious than RC0 and RC1.
- RC3 refers to all Refusal Codes that have been designated as Type 1 Non-Serious RC. These codes are less serious than the RC0, RC1 and RC2 codes.
- RC4 refers to Refusal Codes that have been designated as
  Type 2 Non-Serious. These codes are the least serious codes,
  less serious than the RC0, RC1, RC2 and RC3 codes.

# 3.8.3. Purpose

It has long been desirable to make more granular distinctions among the Refusal Codes. For many years, DOS has maintained a distinction between serious and non-serious codes; these different categories were correlated with different YOB search ranges. However, a mechanism for making greater distinctions will provide greater flexibility in delimiting the set to be retrieved during the first stage of record analysis. The introduction of five refusal code levels also provides the opportunity to correlate more year-of-birth ranges to the refusal code levels.

#### 3.8.4. Function

The RCL provides information needed for the evaluation of record proximity in the Arabic filtering process and contributes to the delimitation of database records retrieved through the RL/YOB Data Store.

# 3.9. YEAR-OF-BIRTH RANGE DATA STORE DECOMPOSITION

#### 3.9.1. Identification

This data store is known as the Year-of-Birth Range Data Store (YR).

#### 3.9.2. **Type**

- 3.9.2.1. It is recommended that the YR be a parameter file, which can be accessed by the client so YOB ranges can be set. Alternatively, it could be represented as a system parameter whose value(s) are set in an .ini file.
- 3.9.2.2. The YR will define the YOB ranges that will be associated with a Refusal Level (see Section 3.8).
- 3.9.2.3. This data store has the following format:

ANA-E Language Analysis Systems, Inc.

48

Figure 26: Format: Year-of-Birth Range Data Store (YR)

Figure 20. Tormat		Town Dovar	VALUE	DATA DEFINITION
DATA FIELD	DATA TYPE	FIELD SIZE	VALUE	exact date of birth
YOB0	integer	1		exact year, inverted month and day
YOBI	character	1	A	exact year, inverted mental
YOB2	character	1	B	exact year of out
	integer	2	199	narrow year of birth range
YOB3		1 2	199	standard year of birth range
YOB4	integer	<del></del>	199	wide year of birth range
YOB5	integer	+ <del>-</del>	199	unlimited year of birth range
YOB6	integer		1	

the same

# 3.9.2.3.1. Definitions

- 3.9.2.3.2. DATA FIELD: YOB# is the Year-of-Birth Range category whose value indicates the year-of-birth range to be searched. The year-of-birth VALUE indicates the search range, that is, the number of years on either side of a given year-of-birth to be searched. For example, if the input year is 1962 and YOB3 range is 4, the search will cover a range of nine years, 1958-1966. The range includes the full year, so all of 1958 and all of 1966.
  - 3.9.2.3.2.1. There are seven YOB# categories, YOB0, YOB1, YOB2, YOB3, YOB 4, YOB5, YOB6.
    - YOB0 is a single integer that refers to an exact month, day, year of birth. If YOB0 is specified, the system must be able to match the month, day and year of the Date of Birth of an input record and a database record.
    - YOB1 is a single character (A) that refers to an exact year-of-birth with the month and day inverted.
      - If YOB1 is specified, the system must be able to match the year of Date of Birth and an inverted month and day (DEC 03 → MAR 12) of the input record and the database record.
      - YOB1 will be relevant to the Arabic Filter and Sorter, but may not function as a search parameter since the value would be subsumed in YOB2.
    - YOB2 is a single character (B) that refers to an exact year-of-birth. If YOB2 is specified, the system must be able to match the year of the Date of Birth of an input record and a database record.
    - YOB3 is a one- or two-place integer (1...99) that refers to a narrow year-of-birth range. Narrow yearof-birth range is usually defined as 1 year (for a search ránge of 3 years).

- YOB4 is one- or two-place integer (1...99) that refers to a standard year-of-birth range. Standard year-of-birth range is usually defined as 3 years (for a search range of 7 years).
- YOB5 is a one- or two-place integer (1...99) that refers to a wide year-of-birth range. Wide year-ofbirth range is usually defined as 5 years (for a search range of 11 years).
- YOB6 is a one- or two-place integer (1...99) that refers to an unlimited or extremely wide year-of-birth range. Unlimited year-of-birth range would be set sufficiently high to include all (or all desired) years-of-birth in the database (e.g., 50).

#### 3.9.3. Purpose

This YR provides a greater granularity in the year-of-birth range and, therefore, greater flexibility in delimiting the set to be retrieved during the first stage of record analysis. The correlation of five refusal code levels to different year-of-birth ranges will help to delimit the number of records to be searched and to define the more valuable set of records.

#### 3.9.4. Function

- 3.9.4.1. The YR permits greater granularity in the Date-of-Birth types related to the system.
- 3.9.4.2. The YR will be accessed by the Refusal Code Level/YOB Range Data Store, which will limit the retrieval range in the Arabic Search Engine.
- 3.9.4.3. The YR will contribute to the Arabic Filter and Sorter to contribute information to the composite score.

# 3.10. REFUSAL CODE LEVEL / YOB RANGE DATA STORE MODULE DECOMPOSITION

#### 3.10.1. Identification

This data store is known as the Refusal Code Level/YOB Range Data Store (RLYOB).

# 3.10.2. Type

- 3.10.2.1. The RLYOB is a matrix that merges the values in the Refusal Code Level (RCL) Data Store and the Year-of-Birth Range (YR) Data Store.
- 3.10.2.2. For each Refusal Level (RL), a Year-of-Birth (YOB) Range is specified.
  - 3.10.2.2.1. Only one YOB Range for each RL is permitted.
  - 3.10.2.2.2. The same YOB Range may apply to more than one RL.

# 3.10.2.3. The RLYOB has the following format:

Figure 27: Format: Refusal Level/Year-of-Birth Range Data Store (RLYOB)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE	DATA VALUE
RL#	character	3	RL04	RL0, RL1, RL2, RL3, RL4
YOB#	character	4	YOB06	YOB0, YOB1, YOB2, YOB3, YOB4, YOB5, YOB6

Figure 28: Example: RLYOB Data Store

RL#	YOB#
RL0	YOB5
RL1	™. YOB4
RL2	YOB3
RL3	YOB3
RL4	YOB2

- 3.10.2.4. Definitions:
- 3.10.2.5. RL#: is a character string that indicates the Refusal Level of the Refusal Code.
- 3.10.2.6. YOB#: is a character string that indicates the Date-of-Birth Range Category of the comparands.

#### 3.10.3. Purpose

Retrieval of records from the database should be delimited by a relationship between the Refusal Code Level and the Year-of-Birth Range. It will restrict the number of records to be reviewed.

#### 3.10.4. Function

The RLYOB is a resource for the Arabic Search Engine to delimit the records retrieved from the database.

## 3.11. COUNTRY-OF-BIRTH PROXIMITY DATA STORE DECOMPOSITION

### 3.11.1. Identification

This data store is known as the Country-of-Birth Proximity Data Store (COBPROX).

#### 3.11.2. Type

- 3.11.2.1. The COBPROX is a matrix whose cells contain a decimal that reflects the degree of relationship between the country represented on the x-axis and the country represented on the y-axis.
- 3.11.2.2. The COBPROX has the following format:

Figure 29: Format: COBPROX Data Store

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE	DATA VALUE
COB#1	character	4	alphabetics	COB Code
COB#2	character	4	alphabetics	COB Code
COBVAL	decimal	4	0.001.00	Various

Figure 30: Example: Piece of COBPROX Data Store

COB#1	COB#2	COBVAL
AGS	AGS	1.00
AGS	ALG	0.05
AGS	MORO	0.05
AGS	SARB	0.05
AGS	SYR	0.05
ALG	ALG	1.00
ALG	MORO	0.85
ALG	SARB	0.75
ALG	SYR	0.75
MORO	MORO	1.00
MORO	SARB	0.75
MORO	SYR	0.75
SARB	SARB	100
SARB	SYR	. 0.75
SYR	SYR	1.00

#### 3.11.2.3. Definitions:

- 3.11.2.3.1. COB#1: is the 4-character COB Code of one of the comparands.
- 3.11.2.3.2. COB#2: is the 4-character COB Code of one of the comparands.
- 3.11.2.3.3. COBVAL: is the decimal value assigned through the ACOB (and other COB Category Data Stores).

# 3.11.3. Purpose

The COBPROX Data Store provides information on the relative value of the COBs in two comparands. This value can serve to limit the COBs that are accessed for retrieval.

#### 3.11.4. Function

The COBPROX is populated by the ACOB and any other partition-specific Country-of-Birth Category Data Stores. The COBPROX provides COB relationship information.

# 3.12. ARABIC COUNTRY-OF-BIRTH CATEGORY DATA STORE DECOMPOSTION

#### 3.12.1. Identification

This data store is known as the Arabic Country-of-Birth Category Data Store (ACOB).

#### 3.12.2. Type

.: -ور.

This ACOB is a data store that will be serve as the source of information for the COBPROX Data Store, supplying the COBVAL, and will provide the COB Category (COBCAT) necessary for the Arabic Filter and Sorter.

Figure 31: Format: Arabic Country-of-Birth Category Data Store (ACOB)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE	DATA VALUE
COB#1	characters	4	alphabetics	COB Code
COB#1	characters	4	alphabetics	COB Code
COBCAT	characters	5	alphanumberics	COB1COB99
COBVAL	decimal	4	0.001.00	Variouş

#### 3.12.3. Definitions

- 3:12.3.1. COB#1: is the 4-character COB Code of one of the comparands.
- 3.12.3.2. COB#2: is the 4-character COB Code of one of the comparands.
- 3.12.3.3. COBCAT: is the category assigned to the relationship of two COBs.
  - 3.12.3.3.1. Categories might include such relationships as Exact, State, Geographic Region, Dialect Region.
  - 3.12.3.3.2. All relationships are adjustable.
- 3.12.4. COBVAL: is the decimal value that will be assigned to a particular COB relationship; this value will be used to determine the COBs that will be permitted in the retrieval process.
- 3.12.5. Example COB Categories might be:

COB1: Exact represents an exact match of the COBs: ALG/ALG; the COBPROXVAL would be 1.00.

COB2: Western Dialect Region represents the set of COBs that are in close geographic proximity and share naming conventions: ALG/MORO. The score would be something less than that applied to an exact match but nonetheless high: 0.85.

COB3: Arabic Partition represents all COBs within the Arabic partition. The value assigned would be less than that for COB2: 0.75.

COB4: All refers to all COBs and is assigned a value that will allow the search of all COBs; it would be the lowest decimal value used.

# 3.12. ARABIC COUNTRY-OF-BIRTH CATEGORY DATA STORE DECOMPOSTION

#### 3.12.1. Identification

This data store is known as the Arabic Country-of-Birth Category Data Store (ACOB).

#### 3.12.2. Type

.\_9.0.

This ACOB is a data store that will be serve as the source of information for the COBPROX Data Store, supplying the COBVAL, and will provide the COB Category (COBCAT) necessary for the Arabic Filter and Sorter.

Figure 31: Format: Arabic Country-of-Birth Category Data Store (ACOB)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE	DATA VALUE
COB#1	characters	4	alphabetics	COB Code
COB#1	characters	4	alphabetics	COB Code
COBCAT	characters	5	alphanumberics	COB1COB99
COBVAL	decimal	4	0.001.00	Various

#### 3.12.3. Definitions

- 3.12.3.1. COB#1: is the 4-character COB Code of one of the comparands.
- 3.12.3.2. COB#2: is the 4-character COB Code of one of the comparands.
- 3.12.3.3. COBCAT: is the category assigned to the relationship of two COBs.
  - 3.12.3.3.1. Categories might include such relationships as Exact, State, Geographic Region, Dialect Region.
  - 3.12.3.3.2. All relationships are adjustable.
- 3.12.4. COBVAL: is the decimal value that will be assigned to a particular COB relationship; this value will be used to determine the COBs that will be permitted in the retrieval process.
- 3.12.5. Example COB Categories might be:

COB1: Exact represents an exact match of the COBs:

ALG/ALG; the COBPROXVAL would be 1.00.

COB2: Western Dialect Region represents the set of COBs that are in close geographic proximity and share naming conventions: ALG/MORO. The score would be something less than that applied to an exact match but nonetheless high: 0.85.

COB3: Arabic Partition represents all COBs within the Arabic partition. The value assigned would be less than that for COB2: 0.75.

COB4: All refers to all COBs and is assigned a value that will allow the search of all COBs; it would be the lowest decimal value used.

ANA-E Language Analysis Systems, Inc.

# 3.12. ARABIC COUNTRY-OF-BIRTH CATEGORY DATA STORE DECOMPOSTION

#### 3.12.1. Identification

This data store is known as the Arabic Country-of-Birth Category Data Store (ACOB).

#### 3.12.2. Type

والساؤل و

This ACOB is a data store that will be serve as the source of information for the COBPROX Data Store, supplying the COBVAL, and will provide the COB Category (COBCAT) necessary for the Arabic Filter and Sorter.

# SOFTWARE DESIGN DESCRIPTION FOR THE HISPANIC NAME SEARCH ALGORITHM

(HNA - E)

### 1. INTRODUCTION

#### 1.1. Purpose

eritektu eret

The current VLDB consists of about 5 million refusal records. The outlook envisions significant growth of the database in the near future and continued growth as more and more data are shared with other Government agencies. Currently, between 45% and 50% of the records have a country of birth from the Hispanic world, about 2.5 million records. These proportions are unlikely to change as the database expands.

Additionally, the character of Hispanic personal names is such that they are both dense and complex. Dense means that there are a relatively few individual surnames that account for the vast majority of surname occurrences. That is, the 500 most frequently occurring distinct surnames account for over 70% of all distinct surnames in the database. The surnames of well over 50% of the records contain only high frequency surnames. Another 25-30% contain at least one of the high frequency surnames. Complex means that Hispanic surnames generally contain more than 1 surname, the first of which is the family name, the second a matronymic (FLORES GOMEZ). Approximately 75% of the surnames from the Hispanic partition contain 2 surname stems (not including affixes like DE, DE LOS). Another 23% have only 1 surname stem. (The remaining records have 3-6 stems.)

The frequency of the names, the high portion of the VLDB and the syntactic variation that can occur in these names (inversion of the names, deletion of a name) argue for special handling of the Hispanic name search process.

The most important aspect of this specialized Hispanic name search algorithm is an efficient High Frequency Name Processor. Retrieval of fewer records for evaluation, yet ones that reflect some variation, is the goal of the High Frequency Processor.

The High Frequency Processor (HFP) of the HNA-E system targets the efficient processing of the most frequently occurring records in the Hispanic portion of the database. Early attempts at developing a processor that would handle high frequency Hispanic names had several major weaknesses.

- The earlier processors did not adequately address the characteristics of Hispanic names. In the name of performance, they did not allow for any variation in high frequency names.
- There was only one access method to the high frequency processor, which eliminated the processing of names similar to the high frequency names by the High Frequency Processor.
- Strict, often unmotivated, limitations were placed on the high frequency retrieval process. Little to no spelling or syntactic variation was permitted.
- The number of records retrieved was often extremely high, which resulted in a significant amount of post-processing.

All of these issues have been addressed in the HNA-E design. The HFP will be primarily list-based but the lists are empirically developed. It will identify and store relevant information about names, variants and their degree of proximity and will apply record similarity criteria before retrieval.

Low frequency Hispanic names, on the other hand, carry more information value because they are less usual. However, even low frequency names occur with sufficient frequency to challenge the system; the Hispanic database in general is very large. Preprocessing low frequency names will, therefore, also help reduce the number of records retrieved by limiting the search criteria.

#### 1.2. Scope

ar de

The HNA-E system is intended to provide special and unique handling for names identified as Hispanic by the Automatic Name Classifier (ANC-E). It addresses the problem of highly frequent names to maximize retrieval potential and minimize the impact on performance and handles less frequently occurring names differently to accommodate the greater information content in these names. It also allows for broad variation in low frequency names and identifies potentially relevant records before database retrieval.

The input into the HNA-E system will be the output of the Advanced Name Classifier (ANC-E). ANC-E will determine if a name is Hispanic and therefore will undergo special processing by the Hispanic Name Algorithm (HNA-E). The design description of the ANC-E is contained as Attachment A in LAS Linguistic Memorandum CT970044 (May 30, 1997).

It became clear during the research for this design that the data stores that would be seminal to this system were very large. The Low Frequency Surname Type Data Store, for example, has over 90,000 records in it. Well over 37,000 of these names occur one time in the database; many of these are obvious misspellings or truncations of names. That is, the character strings do not occur in Spanish: RRODRIGUEZ, for example. It is suggested that a program of data stewardship be initiated to increase the efficiency of the system and reduce the storage needed for deviant material. One method of introducing data stewardship at this juncture would be to introduce Base

HNA-E Language Analysis Systems, Inc.

Records for the database records with errors and make the current database record of the new Base Record.

1.3. Definitions and Acronyms

ANC-E	Advanced Name Classifier for CLASS-E
DELETE	The name segment is completely disregarded in the remainder of the name search process
	and contributes minimal information to the record evaluation process; do not remove the
	segment from the record
DISREGARD	The name segment is disregarded in the remainder of the name search process but
	contributes to the evaluation of the name in the record evaluation process; do not remove
	the segment from the record
DI_KEY	Digraph Key (low frequency name types)
DI_VAL	Digraph Value (two-place decimal indicating digraph relation of two comparands.
F	Female
FNU	First Name Unknown
FPD	Frequency Path Director
FTI	Frequency Type Identifier
GN	Given Name
GNDR	Name Gender
GNTHR	Given Name Threshold (filter qualification)
GN_INIT	Given Name Initial Key
GN_VAL	Final Given Name Value
HCD	Hispanic Character Data Store
HDM	Hispanic Decision Matrix
HFGN KEY	High Frequency Given Name Key (SET_ID of the GN_TYPE)
HFGV	High Frequency Given Name Variant Data Store
HFGN_VAR	High Frequency Given Name Variant Key
HF	High Frequency
HFP	High Frequency Processor
HFS	Hispanic Filter and Sorter
HFSN_KEY	High Frequency Surname Key (SET_ID of the HFSN_TYPE)
HFSN VAR	High Frequency Surname Variant Key (ID_NO of the HFSN_VAR)
HFST	High Frequency Surname Type Data Store
HFSV	High Frequency Surname Variant Data Store
HGI	Hispanic Gender Identifier
HGT	Hispanic General Administration of the Hispanic Given Name Type Data Store
HNA-E	Hispanic Name Search Algorithm for CLASS-E
HNF	Hispanic Name Formatter
HNP	Hispanic Name Preprocessor
	Hispanic Given Name Type Data Store
HNT	Hispanic Parameter Data Store
HPD	Hispanic Regularization Rule Base
HR	Hispanic Rule Engine
HRE	
HSE	Hispanic Search Engine Hispanic Segment Positioner
HSP	Hispanic Segment Positioner
HSS	Hispanic Surname Segmenter
HTD	Hispanic TAQ Data Store
HTP .	Hispanic TAQ Processor
ID_NO	Identification Number for Segments in Data Stores
INITGN	Given Name Initial Parameter Value

retisku retisk

### PROCESS FLOW

A Hispanic name is pre-processed and prepared for key generation. Prefixes are removed, certain name segments are moved, record gender is determined and other name characteristics are collected.

The processor to which a name is submitted is dependent on the frequency of the surname, high frequency or low frequency. There are multiple entries into the High Frequency Processor, which means that low frequency names that are related to high frequency names can also be treated as high frequency names.

The underlying principle behind the handling of high frequency names is that they retrieve a specified set of variants, all of which have pre-determined digraph values associated with them. This places the processing burden on adding records to the system and reduces the burden at the time of the query. Record retrieval criteria have been defined according to the values of the names and their relative positions in the query string, a query with high frequency names will, therefore, retrieve a smaller set of relevant names. The goal is to retrieve an adequate range of names as rapidly as possible.

Variants of low frequency names will be identified before retrieval based on matching digraph keys. The system will then retrieve exact matches on the set of low frequency names that pass a low frequency threshold.

#### MODULE DECOMPOSITION

3.1. HISPANIC NAME SEARCH ALGORITHM FOR CLASS-E MODULE DECOMPOSITION

#### 3.1.1. Identification

This program is known as the Hispanic Name Search Algorithm for CLASS-E (HNA-E)

#### 3.1.2. Type

age of

This program is a subprogram of the CLASS-E system and will process Hispanic names for both queries and record adds.

#### 3.1.3. Purpose

HNA-E will process input names identified as Hispanic by the ANC-E using techniques that are appropriate for Hispanic names. No names with Last Name Unknown (LNU) will be processed by HNA-E.

#### 3.1.4. Function

The Hispanic Name Search Algorithm for CLASS-E (HNA-E) consists of three program modules:

- the Hispanic Name Preprocessor (HNP),
- the Hispanic Search Engine (HSE), and
- the Hispanic Filter and Sorter (HFS).
- 3.1.4.1. The HNP will manipulate an input name to generate search keys, generate additional query forms or alias record adds, calculate record gender, collect information about the input name and its name segments and determine the frequency path to which a name will be submitted for processing.
  - 3.1.4.1.1. The HNP will pass an input name to one of two processing paths:
    - the High Frequency Name Processor (HFP) or
    - the Low Frequency Name Processor (LFP).
  - 3.1.4.1.2. The HNP will generate a set of record criteria and search keys for retrieval of records from the database.

- 3.1.4.2. The HSE will build the retrieval keys, extract record information relevant to the retrieval and retrieve database records according to the keys and criteria identified.
- 3.1.4.3. The HFS will evaluate the database records and will prepare an ordered set of records for return to the user.
  - 3.1.4.3.1. The HFS will qualify records based on filtering criteria and parameters.
  - 3.1.4.3.2. The HFS will sort the qualifying database records into an ordered list with the names most closely proximate to the query name at the top.

## 3.1.5. Subordinates

. وجوزوند.

HNA-E consists of 3 major programming modules: (See Pages 7-10 for graphic representations of the processing flow of these modules.)

- Hispanic Name Preprocessor (HNP),
- Hispanic Search Engine (HSE), and
- Hispanic Filter and Sorter (HFS).

HNA-E Language Analysis Systems, Inc.

# 3.2. HISPANIC NAME PREPROCESSOR MODULE DECOMPOSITION

#### 3.2.1. Identification

This module is known as the Hispanic Name Preprocessor (HNP).

#### 3.2.2. Type

The HNP is a subprogram of the HNA-E program that accepts input from the Advanced Name Classifier for CLASS-E (ANC-E) and prepares it for handling by the Hispanic Search Engine (HSE). (See Section 3.13.)

#### 3.2.3. Purpose

Hispanic names account for almost 50% of the VLDB name records. In addition to the volume of occurrence, there are many names that occur very frequently. The format of Hispanic names contributes further obstacles to name searching: the surname generally consists of two names and the given names generally consists of two names. The most highly frequently occurring prefix in the VLDB is also Hispanic: DE. The frequency, density and the nature of the name argue for preparing the name in whatever way(s) are necessary to expedite the retrieval process. That is the function of the HNP.

#### 3.2.4. Function

- 3.2.4.1.The HNP will prepare a name identified as Hispanic by the ANC-E for the HSE by
  - identifying name segments and determining their disposition,
  - manipulating the name segments to generate additional query formats
  - determining name length and record gender,
  - specifying the frequency character of each name segment and
  - generating search keys.
- 3.2.4.2. Because of the significant amount of information that is to be generated and collected about the name through the HNP, it is strongly recommended that the name be treated as an object that "knows" what sorts of information it needs. Such an object will provide a mechanism for following the acquisition of information as the object passes through the system. Much of that information will be collected and loaded during the HNP stage.

#### 3.2.5. Subordinates

The HNP has ten subordinate functions:

- Name Length Determiner (NLD)
- Hispanic Surname Segmenter (HSS)
- Hispanic TAQ Processor (HTP)

# 3.3. NAME LENGTH DETERMINER MODULE DECOMPOSITION

### 3.3.1. Identification

This function is known as the Name Length Determiner (NLD).

#### 3:3.2. Type

The NLD is a function that accepts as input a surname (SN) segment and stores the surname length. The length will be used by the Hispanic Surname Segmenter (Section 3.4).

### 3.3.3. Purpose .

Name segment length will provide information that will be used by the Hispanic Surname Segmenter to attempt to divide surnames over a specific length into component segments.

# 3.3.4. Function

- 3.3.4.1. The NLD will accept as input each SN segment.
  - 3.3.4.1.1. A segment is a string of characters surrounded by white space.
  - 3.3.4.1.2. The NLD will count the number of characters in SN segment (not including surrounding blanks).
  - 3.3.4.1.3. The NLD will store the length count associated with each SN segment.

# 3.3.5. Subordinates

None.

# 3.4. HISPANIC SURNAME SEGMENTER MODULE DECOMPOSITION

# 3.4.1. Identification

This function is known as the Hispanic Surname Segmenter (HSS).

#### 3.4.2. Type

The HSS attempts to divide surnames over a specified length into component segments. The HSS is a function that must follow the NLD and precede the Hispanic TAQ Processor (Section 3.5).

### 3.4.3. Purpose

Hispanic names often have many segments and these segments may be quite long. Field lengths of fixed size may not be able to accommodate the number of name segments that occur. Data entry operators often attempt to reduce the name length by conjoining name segments. Conjoined segments have an especially negative impact on the surname. The access point into the database

is through the surname and conjoined name segments generally make the component segments inaccessible to processing. Separating conjoined surnames would, therefore, improve the search process.

#### 3.4.4. Function

- 3.4.4.1. The HSS will separate conjoined HF SN segments from a surname segment of nine characters or more in length.
  - 3.4.4.1.1. The HSS will generate additional query records for the separated SN segment and tag the items separated.
  - 3.4.4.1.2. The HSS will generate alias record adds for the separated SN name segments.
- 3.4.4.2. The HSS will access the High Frequency Surname Type Data Store (HFST).
  - 3.4.4.2.1. Phase 1: The HSS will begin with the leftmost character of the query/add SN segment and attempt to identify a HFSN\_TYPE within the input SN string.
  - 3.4.4.2.2. The HSS will choose the longest HFSN\_TYPE that it can identify, separate that string from the input string and proceed to Phase 2.
  - 3.4.4.2.3. Phase 2: The HSS will begin with the rightmost character of the query/add SN segment and attempt to identify a HFSN\_TYPE (in reverse order) within the remaining input string (after any HFSN\_TYPE has been removed during Phase 1).
  - 3.4.4.2.4. The HSS will choose the longest HFSN\_TYPE that it can identify and separate that string from the remaining input string.
  - 3.4.4.2.5. Any residual segment will be retained as is.
  - 3.4.4.2.6. If no HFSN\_TYPE can be identified in either Phase, no action will be taken.
  - 3.4.4.2.7. An alias (or additional query) will be generated for the divided string.

Figure 1: Example: Hispanic Surname Segmenter

INPUT NAME	HFSN TYPE	PHASE 1	PHASE 2	OUTPUT
GARCIAGOMEZ	GARCIA GOMEZ	GARCIA	GOMEZ	GARCIA GOMEZ
PEREZDELOPEZ	PEREZ LOPEZ	PEREZ	DELOPEZ	PEREZ DE LOPEZ
BOMEZDEPEREZ	PEREZ	BOMEZDE	PEREZ	BOMEZDE PEREZ
RAMIREZDELAPAZ	RAMIREZ PAZ	RAMIREZ	DELAPAZ	RAMIREZ DELA PAZ

# 3.4.5. Subordinates

None.

3.5. HISPANIC TITLE/AFFIX/QUALIFIER (TAQ) PROCESSOR MODULE DECOMPOSITION

#### 3.5.1. Identification

This module will be known as the Hispanic Title/Affix/Qualifier Processor (HTP).

#### ·3.5.2. Type

411

The HTP is a process that accepts a full Surname (SN) or Given Name (GN), accesses the Hispanic TAQ Data Store and reduces name fields with multiple segments to their name stems.

#### 3.5.3. Purpose

Hispanic names frequently contain peripheral name elements, such as DE, DE LA, DEL, SAN. Matching on these segments is not generally useful; the name segments with information value are the name stems. For example, GARCIA is the more valuable segment in the string DE GARCIA, as is ANGELES in DE LOS ANGELES. Removal of or disregard for the peripheral name elements allows more emphasis to be placed on the name stems, thus improving the search process.

#### 3.5.4. Function

- 3.5.4.1. The HTP will access the Hispanic TAQ Data Store (HTD) to identify TAQ segments: titles (e.g., SR., MR.), affixes (e.g., DE) or qualifiers (e.g., PH.D., HIJO).
  - 3.5.4.1.1. The HTD will contain information about the disposition of the TAQ.
  - 3.5.4.1.2. The HTD will contain information about the type of TAQ (TAQ\_TYPE): Title, Prefix, Infix, Suffix, Qualifier.
- 3.5.4.2. The HTP will scan all SN segments or all GN segments for any TAQ segments.
  - 3.5.4.2.1. The HTP will begin with the leftmost character of the SN or GN field and attempt to identify a TAQ segment among the SN segments and among the GN segments. (The TAQ segment will be surrounded by white space.)
  - 3.5.4.2.2. If the HTP identifies a segment, it will tag the segment with the ID\_NO and disposition, as indicated in the HTD.
  - 3.5.4.2.3. If the following segment is also a TAQ segment, it will tag the segment with the ID\_NO and disposition, as indicated in the HTD.

- 3.5.4.2.4. This will continue until all *consecutive* TAQ segments have been tagged.
- 3.5.4.2.5. When the HTP encounters a following segment that is not a TAQ segment, it will treat that segment as a stem.
  - 3.5.4.2.5.1. Each TAQ segment identified up to that point will be given the TAQ\_TYPE P (prefix) and each will be associated and stored with the following stem.
- 3.5.4.2.6. The HTP will move to the next segment following the stem and will repeat the TAQ identification process.
  - 3.5.4.2.6.1. The HTP will tag all TAQ segments with the ID\_NO and disposition.
  - 3.5.4.2.6.2. When the HTP encounters a stem, it will tag each TAQ segment (not yet associated with a stem) with the TAQ\_TYPE P and will associate and store each TAQ segment with the following stem.
- 3.5.4.2.7. If HTP encounters a TAQ segment or segments that has no following stem, it will access the HTD to determine if the TAQ type is a Suffix (S).
  - 3.5.4.2.7.1. If the TAQ has a TAQ\_TYPE S, the TAQ will be associated and stored with the preceding stem.
  - 3.5.4.2.7.2. The preceding stem may already have prefixal TAQs.
  - 3.5.4.2.7.3. If the TAQ type is not equal to S, the TAQ will be tagged a Stranded Prefix.
- 3.5.4.3. The HTP will process any TAQ segments identified according to the treatment indicated in the HTD.
- 3.5.4.4. Treatment options include DELETE, DISREGARD and REMOVE.
  - 3.5.4.4.1. **DELETE** means that the segment is completely disregarded in the remainder of the name search process and contributes marginal information to the filtering process. (N.B. The segment is not deleted from the record.)
  - 3.5.4.4.2. **DISREGARD** means that the segment is disregarded in the remainder of the name search process but contributes to the evaluation of the name in the filtering processes.
  - 3.5.4.4.3. **REMOVE** means that a segment that is conjoined to the name stem is removed from that stem. It is then submitted to additional handling, either DELETE or DISREGARD.
    - 3.5.4.4.3.1. The HTP will begin with the leftmost character in the input stem segment (after free-standing TAQs have

- been removed) and will attempt to identify all TAQ segments that have been marked for removal (REMOVE).
- 3.5.4.4.3.2. The HTP will begin with the longest TAQ segment and attempt to remove that; it will then proceed to shorter segments.
- 3.5.4.4.3.3. If the segment that is to remain after TAQ removal is two characters or fewer, the HTP will not remove the
- 3.5.4.4.3.4. If the TAQ segment is identified and the residual stem is of sufficient length, it is separated from the stem.
- 3.5.4.4.3.5. The HTP assigns and stores the ID\_NO of the removed TAQ.
- 3.5.4.4.3.6. The HTP then submits the removed TAQ to the treatment indicated (DELETE or DISREGARD) in the HTD and tags and stores the TAQ with that treatment indicator.

Figure 2: Example: TAQ REMOVE Process

INPUT STRING     TAY REMOVE     DE CORDOBA       DECORDOBA     DE     DELOS ANGELES       DELOSANGELES     DE     DE ARING	Figure 2: Example: TAC	REMOVE FIOCESS	OUTPUT
DECORDOBA  DECORDOBA  DELOS DELOS ANGELES  DELOS ARING	TAIDUT STRING	TAQ REMOVE	
DELOS ANGELES  DELOS ANGELES  DE DE ARING

# 3.5.5. Subordinates

None.

HNA-E Language Analysis Systems, Inc. 16

# 3.6. HISPANIC SEGMENT POSITIONER MODULE DECOMPOSITION

#### 3.6.1. Identification

This function is known as the Hispanic Segment Positioner (HSP).

3.6.2. **Type** 

The HSP is a function that moves a high frequency (HF) surname (SN) found in the given name (GN) field into the SN field.

3.6.3. Purpose

Surnames that occur in the GN field deprive the match process of relevant SN information. Moving a SN segment that occurs in the GN field to the SN field will benefit the search process. (The SN segment is moved to the rightmost position to retain the value assigned to the resident SN segment(s).)

## 3.6.4. Function

- 3.6.4.1. If more than one GN segment (stem) occurs in the GN field, the HSP will determine if the final (rightmost) segment in the GN string is a HF SN
- 3.6.4.2. The HSP will move the segment to the SN field.
  - 3.6.4.2.1. If more than one GN segment occurs in the GN field, the HSP will access the High Frequency Surname Type Data Store (HFST) to determine if the rightmost GN segment is a HFSN\_TYPE.
  - 3.6.4.2.2. If the segment is a HFSN\_TYPE, the HSP will move the segment into the rightmost position of the SN field.
- 3.6.4.3. The process applies to one name segment only and is not iterative.

Figure 4: Example: Hispanic Segment Positioner (HSP)

Figure 4. Example. Trispanie degitient : dettet (					
INPUT NAME	HFSN_TYPE	OUTPUT FORMAT			
CASTRO, MARIA LUZ GOMEZ	GOMEZ	CASTRO GOMEZ, MARIA LUZ			
BARRIOS LUNA, JUAN PEREZ	PEREZ	BARRIOS LUNA PEREZ, JUAN			
LOPES ARRIAGA, CARLOS VITRAL		LOPES ARRIAGA, CARLOS VITRAL			
LOI LO ARRESTOTE, CHIEDOU		<u></u>			

- 3.6.4.4. An additional query record is generated with the moved segment; the original record is not changed.
- 3.6.4.5. An alias record add is generated with the moved segment; the original record is not changed.

#### 3.6.5. Subordinates

None.

# 3.7. HISPANIC NAME FORMATTER MODULE DECOMPOSITION

# 3.7.1. Identification

This module is known as the Hispanic Name Formatter (HNF).

#### 3.7.2. Type

- 3.7.2.1. The HNF is a process that generates additional name formats for input records that have more than two surname stems.
- 3.7.2.2. The HNF will follow the HSS, HTP, and HSP.
- 3.7.2.3. The generated formats will serve as the name format for HF name processing and for comparison in the filtering and sorting process.

#### 3.7.3. Purpose

The HNF will limit the number of segments that can occur in the surname field to two in order to maximize the efficient processing of the input name.

# 3.7.4. Function

- 3.7.5. The HNF will generate additional alias record adds and queries for surnames that contain more than two SN stems.
  - 3.7.5.1. The HNF will accept input strings with any number of SN segments (stems).
  - 3.7.5.2. When more than two SN segments are present, the HNF will generate additional name formats with a limit of two SN segments.
    - 3.7.5.2.1. The HNF will begin with the leftmost SN segment and generate dual-SN formats with each additional SN segment.
    - 3.7.5.2.2. The HNF will move to the second SN segment and generate dual-SN formats with each other SN segment that have not yet been generated.
    - 3.7.5.2.3. The relative order of all segments will be maintained.
  - 3.7.5.3. All generated formats will be stored with the record add.
  - 3.7.5.4. All generated formats will be additional queries.

Figure 5: Example: Hispanic Name Formatter (HNF)

INPUT SURNAME	GARCIA	LUNA	BUSTOS	ARRIAGA
HNF DUAL-SN FORMATS	GARCIA	LUNA		<u> </u>
	GARCIA		BUSTOS	<u>l,</u>
	GARCIA			ARRIAGA
		LUNA	BUSTOS	
		LUNA	,	ARRIAGA
			BUSTOS	ARRIAGA

# 3.7.6. Subordinates

None.

# 3.8. SEGMENT POSITION IDENTIFIER MODULE DECOMPOSITION

# 3.8.1. Identification

This module is known as the Segment Position Identifier (SPI).

#### ·3.8.2. Type

The SPI is a function that identifies the relative position of each of the SN and GN stems. The SPI must follow the HTP, HSP and HNF. Segment position information will be accessed by the High Frequency Processor (HFP) and the Hispanic Filter and Sorter (HFS).

# 3.8.3. Purpose

Hispanic names generally contain more than one SN and more than one GN.

The value of each of these name stems is different. In a SN, the leftmost stem is the family name; other SN stems are differentiators. The family name carries more value in the SN. In a GN, the leftmost name stem generally indicates gender so is a valuable indicator. Names that are in- and out-of position are therefore of differing relevance. Position information can contribute to the selection and evaluation of relevant records.

#### 3.8.4. Function

- 3.8.4.1. The SPI will operate on any SN or GN except where dual-SN formats have been generated.
  - 3.8.4.1.1. Where dual-SN formats have been created, the SPI will accept only those formats.
  - 3.8.4.1.2. The SPI will accept any number of GN segments.
- 3.8.4.2. The SPI will specify the position in the name field (SN or GN fields) of each name segment.
- 3.8.4.3. The SPI will begin with the leftmost segment and assign Position 1, proceeding to the next segment and assign Position 2, and so forth.
- 3.8.4.4. Position information will be generated for and stored with each SN segment.
- 3.8.4.5. Position information will be generated for and stored with each GN segment.

#### 3.8.5. Subordinates

None.

# 3.9. HISPANIC GENDER IDENTIFIER MODULE DECOMPOSITION

#### 3.9.1. Identification

This function is known as the Hispanic Gender Identifier (HGI).

### 3.9.2. Type

This is a function that associates a gender value with a **record**; it will be accessed by the Hispanic Decision Matrix (HDM) and the Hispanic Filter and Sorter (HFS).

### 3.9.3. Purpose

It is usually possible to predict the gender of a Hispanic name based on the gender marker of the leftmost given name segment. Because crossed-gender names are of little value in the visa adjudication process, lowering the value of a record whose gender does not match that of a query would improve the name matching process.

Predicting gender based on one source of gender, however, may result in elimination of records that differ by one character only. More than one source of gender information can provide a means of validating the gender assignment. This will be the record gender. Record gender will reduce the chance of qualifying or disqualifying a record based on the gender of a single name segment, which could be misspelled or ambiguous with respect to gender.

## 3.9.4. Function

- 3.9.4.1. The HGI will derive a gender that will be associated with a *record* and not a Given Name stem alone.
- 3.9.4.2. A record gender value may be Male (M), Female (F), or Unknown/Ambiguous (U) Gender.
  - 3.9.4.2.1. The HGI will derive the record gender from the GN gender associated with each GN segment and the gender provided by the user during the data entry process.
    - 3.9.4.2.1.1. The HGI will access the Hispanic Given Name Type Data Store (HGT) to determine the gender associated with each GN segment.
      - 3.9.4.2.1.1.1. If the name is present in the HGT, the gender indicated will be associated with the GN segment.
      - 3.9.4.2.1.1.2. If the name is not present in the HGT, the record gender will be marked as Unknown (U). (This would occur for a query with a name never before submitted to the system.)
    - 3.9.4.2.1.2. The applicant gender is determined at the time of application and must be entered, captured and stored by the system.

- 3.9.4.2.2. The HGI will verify that all gender indicators agree: the gender associated with each GN segment and the applicant gender received at the time of application.
  - 3.9.4.2.2.1. To mark the record gender as M or F, the HGI requires gender validation from a *minimum* of two sources.
  - 3.9.4.2.2.2. All sources of gender information (whether two or more) must match for gender to be marked as M or F.
    - 3.9.4.2.2.1. If the gender indicators match, the match value will become the record gender.
    - 3.9.4.2.2.2.2. If the gender indicators do not match, gender is marked as U.

Figure 6: Example: Record Gender Assignment

GIVEN NAME	HGT GNDR	INPUT GENDER	RECORD GENDER
1) MARIA	F	F	F
LUZ	F		
2) JOSE	M	M	M
ANTONIO	M		
3) CARLOS	M	M	Ŭ
(DE LA) CRUZ	U		
4) BERNARDO	M	M	M
5) CAMEN (misspelling)	(not in HGT)	F	Ŭ
MARIA	F		

#### 3.9.5. Subordinates

None.

# 3.10. FREQUENCY PATH DIRECTOR MODULE DESCRIPTION

#### 3.10.1. Identification

This module is known as the Frequency Path Director (FPD).

# 3.10.2. Type

- 3.10.2.1. The FPD directs a record to the High Frequency Processor or Low Frequency Processor depending on the presence or absence of HF *surnames* in the string.
- 3.10.2.2. The FPD will access the following data stores:
- High Frequency Surname Type Data Store (HFST)
- Hispanic Character Data Store (HCD)

## 3.10.3. Purpose

Many Hispanic names occur with such high frequency that they would benefit from special processing. The system must determine which the high

frequency surnames are and direct records with high frequency surnames to the proper handler.

#### 3.10.4. Function

- 3.10.4.1. The FPD will accept any SN format, except where dual-SN formats have been generated by the Hispanic Name Formatter (HNF).
  - 3.10.4.1.1. The FPD will operate on the dual-SN formats where they have been generated.
- 3.10.4.2. The FPD will identify, process and assign keys to SN initials.
- 3.10.4.3. The FPD will identify and tag each SN stem as HF or LF.
- 3.10.4.4. The FPD will assign HFSN\_KEYs, where appropriate.
- 3.10.4.5. The FPD will direct the record to the HF Processor or LF Processor depending on the frequency tags of the SN segments.
- 3.10.4.6. The frequency-identification process will repeat until the frequency value of all SN segments has been identified.
- 3.10.4.7. Surname Initials
- 3.10.4.8. Record Adds
- 3.10.4.9. The FPD will generate a SN\_INIT Key for the initial character of each SN segment (The SN segment may be an initial).
  - 3.10.4.9.1. The FPD will access the Hispanic Character Data Store (HCD) to identify the SN\_INIT Key.
  - 3.10.4.9.2. The FPD will find the initial character in the CHAR list.
  - 3.10.4.9.3. The FPD will assign the SN\_INIT Key to the character.
  - 3.10.4.9.4. The SN\_INIT Key will be the SET\_ID for all occurrences of the character.
  - 3.10.4.9.5. The FPD will store the SN\_INIT Key with the SN segment of the record.

# 3.10.4.10. Query

- 3.10.4.11. The FPD will identify single characters that occur in the SN field; any segment that has a name length of 1 (as specified by the Name Length Determiner (NLD)) is an initial.
- 3.10.4.12. The FPD will access the Hispanic Character Data Store (HCD) to determine the SN\_INIT Key(s) to assign to the segment.
  - 3.10.4.12.1. The FPD will find each instance of the character in the CHAR\_VAR list.
  - 3.10.4.12.2. The FPD will assign SN\_INIT Key(s) to the SN initial.

- 3.10.4.12.3. The SN\_INIT KEY is the SET\_ID associated with each instance of the initial.
- 3.10.4.12.4. The SN initial may have multiple SN\_INIT Keys.
- 3.10.4.13. The FPD will ignore the SN\_INIT Keys when determining the frequency path assignment of a record; the assignment will be based on the frequency of the other SN segment.

## 3.10.4.14. High Frequency Surnames

- 3.10.4.15. The FPD will access the High Frequency Surname Type Data Store (HFST).
  - 3.10.4.16. If a SN segment matches exactly a HFSN\_TYPE in the HFST, the segment will be given the HFSN\_KEY associated with the HFSN\_TYPE.
    - 3.10.4.16.1. Record Add/Query: The HFSN\_KEY will be the SET\_ID associated with the HFSN\_TYPE in the HFST.
    - 3.10.4.16.2. **Record Add**: A digraph value (DI\_VAL) of 1.00 will be assigned to and stored with the segment that matches a HFSN\_TYPE exactly.
    - 3.10.4.16.3. The HFSN\_KEY will represent a set of name segments that have qualified as digraph variants of the HFSN\_TYPE. (See 3.12.4.38 for information on how the variants are assigned to the same set.)
  - 3.10.4.17. The FPD will direct records that contain all HFSN\_KEYs to the High Frequency Processor (HFP).

Figure 7: Example: Qualification for High Frequency Processor

INPUT NAME:	FIELD	HFSN_KEY	DI_VAL
GARCIA LOPEZ, ANTONIO JESUS			
GARCIA	SN	0001	1.00
LOPEZ	SN	0004	1.00

Figure 8: Resource: Piece of High Frequency Surname Type Data Store (HFST)

ID_NO	HFSN_TYPE	SET_ID
0001	GARCIA	0001
0002	RODRIGUEZ	0002
0003	HERNANDEZ	0003
0004	LOPEZ	0004
0005	MARTINEZ	0005
0006	GONZALEZ	0006
0007	PEREZ	0007
0008	SANCHEZ	0008
0009	RAMIREZ	0009
0010	GOMEZ	.0010
0011		0011

3.10.4.18. The FPD will direct all records that do *not* contain all HFSN\_KEYs to the Low Frequency Processor (LFP).

# 3.10.5. Subordinates

None.

3.11. HIGH FREQUENCY PROCESSOR MODULE DECOMPOSITION

#### 3.11.1. Identification

This module is known as the High Frequency Processor (HFP).

## 3.11.2. Type

- 3.11.2.1. The HFP is a program module that
  - will process records with all HFSN\_KEYs, HFSN\_VAR Keys, SN\_INIT Keys and mixed HF and LF Keys;
  - · will generate Given Name Keys; and
  - will access the Hispanic Decision Matrix Data Store (HDM) to identify retrieval criteria for the HF records.
- 3.11.2.2. Multiple entry points into the HFP will be supported: through the Frequency Path Director and the Low Frequency Processor (LFP).

## 3.11.3. Purpose

Earlier attempts to develop a HF handler for Hispanic names have been limited to processing of records that contain only HF names; little to no variation was permitted. HNA-E will support variation in the processing of HF names by allowing multiple entry points into the HFP.

HNA-E Language Analysis Systems, Inc.

#### 3.11.4. Function

- 3.11.4.1. The HFP will accept names directed to the processor by the Frequency Path Director (FPD) and by the LFP.
- 3.11.4.2. The records accepted will contain all HFSN\_KEYs and/or HFSN\_VAR Keys, SN\_INIT Keys, and mixed HFSN\_KEY/HFSN\_VAR and DI\_KEYs.
- 3.11.4.3. All SN\_INIT Keys passed to the HFP will be treated as segment Keys and will undergo the same criteria identification as other segments.
- 3.11.4.4. If all segments of the SN Field have been given HFSN\_KEYs and/or HFSN\_VAR Keys and related DI\_VALs, the HFP will begin processing the GN segments.

# 3.11.4.5. Processing the Given Name Segments

- 3.11.4.6. If the GN segment is First Name Unknown (FNU), no GN processing will take place.
- 3.11.4.7. High Frequency Given Name Segment Keys

#### 3.11.4.8. Record Adds

- 3.11.4.9. The HFP will access the Hispanic Given Name Variant Data Store (HGNV) to determine if the GN segments are HF GN segments.
  - 3.11.4.9.1. If the GN segment matches one or more variants in the HGNV, the HFP will assign the HFGN\_KEY to the GN segment.
  - 3.11.4.9.2. The HFGN\_KEY is(are) the SET\_ID(s) associated with the variant.
  - 3.11.4.9.3. The HFP will associate the appropriate DI\_VAL with the SET\_ID and GN segment.
  - 3.11.4.9.4. The HFP will store the SET\_ID(s) and their DI\_VAL with the GN segment.
  - 3.11.4.9.5. The HFGN\_KEY ensures that the system will retrieve variants of a HF segment when the HF segment is queried.

#### 3.11.4.10. Query

- 3.11.4.11. The HFP will access the Hispanic Given Name Type Data Store (HGT).
  - 3.11.4.11.1. If a GN segment matches exactly a GN\_TYPE name segment in the HGT and HI\_FREQ = 1 (is True) (that is, the segment is a HF GN\_TYPE segment), the HFP will assign to the GN segment the HFGN\_KEY associated with the GN\_TYPE.

- 3.11.4.11.2. The HFGN\_KEY will be the SET\_ID associated with the HF GN\_TYPE.
- 3.11.4.12. High Frequency Given Name Initial Keys
- 3.11.4.13. The HFP will create one or more GN\_INIT Keys for each HF GN segment.
- 3.11.4.14. The GN\_INIT Key will be the initial key for each GN segment, including initials.
  - 3.11.4.14.1. Record Add

يوزن فن

- 3.11.4.14.2. The HFP will identify the initial character of each GN segment.
- 3.11.4.14.3. The HFP will access the Hispanic Character Data Store (HCD) and will find all occurrences of the character in the CHAR-VAR list.
- 3.11.4.14.4. The HFP will assign the GN\_INIT Key(s) to each GN initial.
  - 3.11.4.14.4.1. The GN\_INIT Key will be the SET\_ID(s) associated with the GN initial (CHAR\_VAR).
  - 3.11.4.14.4.2. The GN segment may have multiple GN\_INIT Keys.
  - 3.11.4.14.4.3. The GN\_INIT Key will permit retrieval of multiple initials for a GN initial.
  - 3.11.4.14.4.4. The HFP will store the GN\_INIT Key(s) for each GN segment initial with the record.
- 3.11.4.14.5. Query
- 3.11.4.14.6. The HFP will access the HCD and find the initial in the CHAR list.
- 3.11.4.14.7. The HFP will identify the GN\_INIT Key for each GN segment initial.
- 3.11.4.15. If the GN segment is not a variant in the HGNV, the HFP will tag the name as LF.
- 3.11.4.16. Low Frequency Given Name Segment Keys
- 3.11.4.17. For each LF GN segment, the HFP will attempt to determine if the segment is a potential variant of a HF GN\_TYPE and will create one or more GN\_INIT Keys for record adds and queries.
- 3.11.4.18. Record Add
- 3.11.4.19. If the LF GN is *not* in the HGNV Data Store, the HFP will determine if the segment is a potential variant of a HFGN\_TYPE. (This

would apply to LF GN segments that are being submitted to the system for the first time.)

- 3.11.4.19.1. If the HFP determines that the HF GN segment is a variant of a HFGN\_TYPE, the LFP will append the segment to the HFGV Data Store.
- 3.11.4.19.2. The HFP will access the Hispanic Given Name Type Data Store (HGT) to determine if the LF GN segment is a digraph variant of one or more of the HF GN\_TYPEs. (That is, the LF GN segment is a digraph variant of the GN\_TYPE whose HF Value is True (1)).
- 3.11.4.19.3. The LFP will perform a digraph evaluation of the LF GN and each HF GN\_TYPE.
- 3.11.4.19.4. The digraph value is determined in the following way:
  - 3.11.4.19.4.1. The digraphs are identified for each segment.
  - 3.11.4.19.4.2. Each pair of alphabetic characters is identified: CARA → CA/AR/RA
  - 3.11.4.19.4.3. A digraph is also formed of the initial boundary (#) and the first alphabetic character: CARA → #C.
  - 3.11.4.19.4.4. A digraph is also formed of the final alphabetic character and the final boundary (#): CARA → A#.
  - 3.11.4.19.4.5. The number of shared digraphs is calculated.
    - 3.11.4.19.4.5.1. A digraph may match one digraph only.
  - 3.11.4.19.4.6. The number of shared digraphs is multiplied by 2 and divided by the total number of digraphs in Comparand #1 added to the total number of digraphs in Comparand #2.
    - 3.11.4.19.4.6.1. The formula is:

2 \* d / a + b, where d = the total number of shared digraphs; where a = the total number of digraphs in Comparand #1; and where b = the total number of digraphs in Comparand #2.

3.11.4.19.4.7. The result is the Digraph Value (DI\_VAL) for the two Comparands.

Figure 9: Example: Digraph Calculation

COMPARANDS	DIGRAPHS	SHARED DIGRAPHS	DI_VAL
COMPARAND#1: CARA	#C CA AR RA A# (5 total digraphs = a)	#C CA AR A#	2*d/a+b= 8/12
COMPARAND #2: CARINA	#C CA AR RI IN NA A# (7 total digraphs = b)	= 4 (d)	0.67

- 3.11.4.19.4.8. This process is performed for each of pair of Comparands.
- 3.11.4.19.5. To qualify for addition to the HFGV as a variant of one or more HFGN\_TYPEs, the digraph value must pass a threshold, the High Frequency Given Name Variant Threshold (HFGV Threshold).
  - 3.11.4.19.5.1. The HFP will access the Hispanic Parameter Data Store (HPD) (Section 4.13) to determine the HFGV Threshold that the digraph value must pass for the LF GN to be appended to the HFGV Data Store.
  - 3.11.4.19.5.2. If the LF GN segment qualifies as digraph variant of one or more HF GN\_TYPEs, the HFP
    - will append the LF GN to the HFGN\_TYPEs to which
      it is related by entering the name into the HFGN\_VAR
      list in the HFGV Data Store;
    - will assign the next available ID\_NO to the newly added HFGN\_VAR;
    - will assign the SET\_ID to the newly added HFGN\_VAR that corresponds to the SET\_ID of the HFGN\_TYPE with which the new HFGN\_VAR is associated;
    - will enter the digraph value into DI\_VAL; and
    - will store with the LF GN segment in the record the ID\_NO(s) of the HFGN\_VAR for each entry, the SET\_ID of each HFGN\_TYPE that is the parent of the HFGN\_VAR, and the digraph value associated with each entry.
- 3.11.4.20. Whether or not the LF segment is a variant of a HFGN\_TYPE, the HFP will generate one or more GN\_INIT Keys for the LF GN segment.
  - 3.11.4.20.1. The GN\_INIT Key will be the initial key for each GN segment, including segments that are initials.
  - 3.11.4.20.2. If the GN segment is FNU (First Name Unknown), no GN\_INIT Key will be generated.

28

3.11.4.20.3. Record Add

HNA-E Language Analysis Systems, Inc.

- 3.11.4.20.4. The HFP will identify the initial character of each GN segment.
- 3.11.4.20.5. The HFP will access the Hispanic Character Data Store (HCD) and will find all occurrences of the character in the CHAR-VAR list.
- 3.11.4.20.6. The HFP will assign the GN\_INIT Key(s) to each GN initial.
  - 3.11.4.20.6.1. The GN\_INIT Key will be the SET\_ID(s) associated with the GN initial (CHAR\_VAR).
  - 3.11.4.20.6.2. The GN segment may have multiple GN\_INIT Keys.
  - 3.11.4.20.6.3. The GN\_INIT Key will permit retrieval of multiple initials for a GN initial.
  - 3.11.4.20.6.4. The HFP will store the GN\_INIT Key(s) for each GN segment initial with the record.
- 3.11.4.20.7. Query

44. 20 6.21

- 3.11.4.20.8. The HFP will access the HCD and find the initial in the CHAR list.
- 3.11.4.20.9. The HFP will identify the GN\_INIT Key for each GN segment initial.
- 3.11.4.20.10. The GN\_INIT Key will be the SET\_ID associated with the CHAR.

Figure 10: Example: HFGN\_KEYs and GN\_INIT Keys (Query)

	- B						
INPUT GN	HF?	HFGN_KEY	GN_INIT				
			KEYS				
MARIO	T	020	078 (M)				
MICHAEL	F		078 (M)				
YSABEL	F		036 (Y, I)				
ZUSANA	F		002 (Z, S)				

Figure 11: Example: HFGN\_KEYs and GN\_INIT Keys (Record Add)

Tigute II. Example: In Civ_IEE Is and Civ_III III							
INPUT GN	HF?	HF VARIANT?	HFGN_TYPE	HFGN_KEY	GN_INIT KEYs

ZUSANA	F	T	SUSANA	436	002 (Z, S)		

- 3.11.4.21. The HFP will direct queries with all HF SN or mixed HF and LF SN (including SN\_INIT Keys) and any GN Keys (HFGN\_KEYs or GN\_INIT Keys) or FNU to the Hispanic Decision Matrix (HDM) to determine the record retrieval criteria.
  - 3.11.4.21.1. Criteria for database retrieval include name content (whether the names are the same or different), the position of the name segments, the YOB range, the Refusal Code Level, Record Gender and additional restrictions based on the GN.

# 3.11.4.22. Hispanic Decision Matrix

- 3.11.4.23. The HFP will access the portion of the HDM that represents the number of HF SN segments in the query name, either one HF SN or two HF SNs
- 3.11.4.24. The HFP will identify and generate the set of SN formats possible for the number of SN segments in the query (one or two).
  - 3.11.4.24.1. The SN formats indicate
    - · position of segments,
    - number of segments, and
    - other segments permitted.
- 3.11.4.25. The HFP will identify the retrieval criteria in the HDM associated with each SN format.
  - 3.11.4.25.1. The retrieval criteria include
    - Year-of-Birth Range
    - Refusal Level and
    - Record Gender
- 3.11.4.26. GN Keys will be carried forward with the retrieval criteria.
- 3.11.4.27. The HFP will send to the Hispanic Search Engine (HSE) the query format(s), all retrieval criteria associated with each query format and all SN Keys and all GN Keys generated for the query.

## 3.11.5. Subordinates

None.

# 3.12. LOW FREQUENCY PROCESSOR MODULE DECOMPOSITION

### 3.12.1. Identification

This module is known as the Low Frequency Processor (LFP).

### 3.12.2. Type

- 3.12.2.1. The LFP is a program module that will process names that contain SN segments identified by the FPD as Low Frequency SN segments (i.e., not found in the HFST Data Stores by the FPD).
- 3.12.2.2. The LFP will access the
  - High Frequency Surname Variant Data Store (HFSV) and
  - Low Frequency Surname Type Data Store (LFST).

#### 3.12.3. Purpose

The LFP will process name segments that are identified as LF SN segments by the FPD. The LFP will determine 1) whether or not the LF segment is a variant of one or more HF SN and 2) whether or not the LF segment has variants among the LF segments listed in the Low Frequency Surname Type Data Store (LFST). The result of these two processes will be a list of segments to use as exact matches for retrieval.

### 3.12.4. Function

# 3.12.4.1. General

- 3.12.4.2. The LFP will accept from the FPD any record with a SN segment that has been tagged as a LF SN.
  - 3.12.4.2.1. The LFP will process records that contain only LF segments *and* all records that contain mixed HF and LF segments.
  - 3.12.4.2.2. The LFP will process records that contain one LF segment and SN\_INIT Keys.
    - 3.12.4.2.2.1. Low frequency processing will be limited to the LF segment.
    - 3.12.4.2.2.2. The SN\_INIT Keys will contribute to the building of LF retrieval keys.
  - 3.12.4.2.3. With mixed HF and LF SN, the LFP will process only the LF SN segment. (The HF segment will have been assigned a HFSN\_KEY by the FPD).
- 3.12.4.3. All LF segments in records that are sent to the LFP will be analyzed for both HF affiliations and LF variants.

### 3.12.4.4. The LFP will attempt

to relate each LF SN segment to one or more HFSN\_TYPEs,

- to identify other LF SN segments related to the input LF SN segment(s), and
- to append LF SN segments to the HFSV and LFST that have not been previously submitted to the system to the HFSV and LFST.
- 3.12.4.5. The LFP will direct a query in which all LF SN segment(s) have been related to HFSN\_TYPEs to the High Frequency Processor (HFP) (see Section 3.11) for generation of GN Keys and submission to the Hispanic Decision Matrix.
  - 3.12.4.5.1. The record may have the format HFSN\_KEY (or SN\_INIT Key) + HFSN\_VAR Key, where the second key relates a LF SN segment to a HFSN\_TYPE.
  - 3.12.4.5.2. The record may have the format HFSN\_VAR Key + HFSN\_VAR Key, where both segments are keys relating a LF SN segment to a HFSN\_TYPE.
  - 3.12.4.5.3. The record may have the format HFSN\_VAR Key, where the only segment is a key relating a LF SN segment to a HFSN\_TYPE.
- 3.12.4.6. The LFP will direct a query record in which all LF SN segments have been related to other LFSN\_TYPEs directly to the Hispanic Search Engine. (SN\_INIT Keys may be present.)
- 3.12.4.7. The LFP will perform the following processes:
  - Access the HFSV Data Store to determine if the LF name segment is variant of a HFSN\_TYPE.
  - Assign HFSN\_VAR Key(s), as appropriate.
  - Generate LF\_KEYs for LF SN variants identified in the LFS Data Store
  - Perform a digraph comparison on the HFST Data Store to determine if a LF SN not in the HFSV Data Store is a digraph variant of a HFSN\_TYPE segment.
- 3.12.4.8. The goal of the LFP, for a query with LF SN segments, is to develop a set of specific names related to the LF SN that will be used as keys for record retrieval.
- 3.12.4.9. Identifying Related High Frequency Surnames
- 3.12.4.10. The LFP will access the HFSV Data Store to determine if each LF SN segment in the input name is a variant of HFSN\_TYPE.
  - 3.12.4.10.1. The LFP will attempt to find all occurrences of the LF SN segment in the HFSN\_VAR list.
  - 3.12.4.10.2. Record Add

- 3.12.4.10.3. If the segment is found in the HFSN\_VAR list, the LFP will assign one or more HFSN\_KEYs and HFSN\_VAR Keys to the LF SN.
  - 3.12.4.10.3.1. The keys will be
    - the HFSN\_KEY: the SET\_ID associated with the HFSN\_TYPE that is the parent of the HFSN\_VAR and
    - the HFSN\_VAR Key: the ID\_NO of the HFSN\_VAR.
  - 3.12.4.10.3.2. The digraph value associated with the HFSN\_TYPE and HFSN\_VAR pair will be retrieved and stored with the HFSN\_KEY and HFSN\_VAR Key as the DI\_VAL.
  - 3.12.4.10.3.3. The LFP will store the HFSN\_KEY, HFSN\_VAR Key and the associated digraph value with the record
    - 3.12.4.10.3.3.1. For example, if GARCA is the LF SN and is a variant of the HFSN\_TYPE GARCIA, then GARCA will be given the SET\_ID associated with the HFSN\_TYPE GARCIA (0001) and the ID\_NO that uniquely identifies GARCA (000137).
    - 3.12.4.10.3.3.2. The associated digraph value (0.77) will be stored with the LF SN GARCA as the DI\_VAL of 0001 and 000137.
  - 3.12.4.10.3.4. There may be multiple HFSN\_KEYs and HFSN\_VAR Keys associated with a single LF SN segment.

3.12.4.10.4. Query

- 3.12.4.10.5. The LFP will attempt to associate the LF SN with one or more HFSN\_TYPEs.
  - 3.12.4.10.5.1. The LFP will access the HFSV and determine if the LF SN is a variant of a HFSN\_TYPE.
  - 3.12.4.10.5.2. If the LF SN is found in the HFSN\_VAR list of the HFSV table, the LFP will assign a HFSN\_VAR Key to the LF SN segment.
    - 3.12.4.10.5.2.1. The HFSN\_VAR Key will be the ID\_NO associated with the HFSN\_VAR (and not the SET\_ID that is associated with the HFSN\_TYPE).
      - 3.12.4.10.5.2.1.1. The LF segment will be associated with the HF segment but with no other name segments in the same HFSN\_TYPE class.
      - 3.12.4.10.5.2.1.2. That is, the variants associated with the HF segment are *not* related to one another through this process.

3.12.4.10.5.3. A LF SN may be a variant of multiple HFSN\_TYPEs and may therefore receive multiple HFGN\_VAR Keys.

3.12.4.10.6. If, by virtue of this process, all LF SN segments in a query are set equal to HFSN\_VAR Keys, the LFP will direct the query record to the HFP (see Section 3.11) for generation of Given Name Keys, submission to the High Frequency Decision Matrix (HDM) and identification of retrieval criteria.

3.12.4.10.7. The LFP will direct all queries and record adds to a LF analysis whether or not the LF SN segment was identified as a variant of a HFSN\_TYPE.

- 3.12.4.11. Identifying Related Low Frequency Surnames
- 3.12.4.12. General
- 3.12.4.13. All records with one or more LF SN segments will undergo LF analysis by the LFP.
- 3.12.4.14. For record adds, the LFP will assign an ID\_NO that will be stored with the record.
- 3.12.4.15. The LFP will generate LFDIKEYs for each LF SN segment in the query.
- 3.12.4.16. The LFP will use the LFDIKEYs to identify related LF SN segments.
- 3.12.4.17. Note that the LFP will not generate LF Keys for the GN portion of the input name.
- 3.12.4.18. LF SN Segment in LFST
- 3.12.4.19. The LFP will determine if the LF SN segment of the input record is in the Low Frequency Surname Type Data Store (LFST).
- 3.12.4.20. Record Add:
- 3.12.4.21. If the LF SN segment is a LFSN\_TYPE in the LFST, the LFP will assign to and store with the LF SN segment the ID\_NO associated with the LFSN\_TYPE.
- 3.12.4.22. Query:
- 3.12.4.23. If the LF SN segment is a LFSN\_TYPE in the LFST, the LFP will retrieve the (up to) 10 digraph keys (LFDIKEYs) that are associated with the name segment in the LFST.
- 3.12.4.24. The LFP will use the LFDIKEYs retrieved from the LFST and the LFDIKEYs stored with all LFSN\_TYPEs in the LFST Data to subset the LFST and to identify potential variants of the input LF SN segment.
- 3.12.4.25. Identifying LF Query Variants
- 3.12.4.26. Phase 1:
- 3.12.4.27. The LFP will subset the LFST Data Store.
- 3.12.4.28. The LFP will select those names from the LFST that share a predetermined set of LFDIKEYs.
  - 3.12.4.28.1. The LFP will determine the number of LFDIKEYs shared between each LFSN\_TYPE and the LF query SN segment.
  - 3.12.4.28.2. The LFP will determine the Shared Key Value based on the number of shared digraphs.
    - 3.12.4.28.2.1. The LFP will use the following formula to determine the Shared Key Value: multiply the number

of shared keys by two and divide by the total number of keys associated with each name:

2 \* [number of shared keys] / (total keys of Comparand #1 plus total keys of Comparand #2)

3.12.4.28.3. The LFP will select only those LFSN\_TYPEs whose Shared Key Value passes the LFDIKEY Threshold.

3.12.4.28.3.1. The LFP will access the Hispanic Parameter Data Store to identify the minimum matching requirement for the Shared Key Value, the LFDIKEY Threshold.

3.12.4.28.3.2. For a segment to qualify for further processing, the Shared Key Value must pass the LFDIKEY Threshold found in the Hispanic Parameter Data Store (HPD).

Figure 19: Example: Phase 1: LF Variants Related to a LF Query SN Segment; LFDIKEY Threshold = 0.40

•	ID_NO		LFDIKEYs	SHARED KEYS	PASS LFDIKEY THRESHOLD 0.40?
QUERY NAME #1		FLORENZAN	FL1/FL2/LO2/LO1/LO3/ OR3/OR2/OR4/RE4/RE3		
LFSN_TYPE	000189	FLORENZAN	FL1/FL2/LO2/LO1/LO3/ OR3/OR2/OR4/RE4/RE3	10 (All)	2*10/20 = 1.00 YES
LFSN_TYPE	000232	FLORESZ	FL1/FL2/LO2/LO1/LO3/ OR3/OR2/OR4/RE4/RE3	10 (All)	2*10/20 = 1.00 YES
LFSN_TYPE	000412	LORENZ	LO1 / LO2 / OR2 / OR1 / OR3 / RE3 / RE2 / RE4 / EN4 / EN3	5 (LO2 / OR2 / OR3 / RE3 / RE4)	2*5/20 = 0.50 YES
QUERY NAME #2		TOREAT	TO1/TO2/OR2/OR1/OR3/ RE3/RE2/RE4/EA4/EA3		
LFSN_TYPE	000714	TOREAT	TO1/TO2/OR2/OR1/OR3/ RE3/RE2/RE4/EA4/EA3	10 (All)	2*10/20 = 1.00 YES
LFSN_TYPE	000652	THORET	TH1 / TH 2 / HO2 / HO1 / HO3 / OR3 / OR2 / OR4 / RE4 / RE3	4 (OR2 / OR3 / RE3 / RE4)	2*4/20 = 0.40 YES
LFSN_TYPE	000776	TOERO	TO1/TO2/OE2/OE1/OE3/ ER3/ER2/ER4/RO4/RO3	2 (TO1 / TO2)	2*2/20 = 0.20 NO

#### 3.12.4.29. Phase 2:

- 3.12.4.30. The LFP will perform a digraph comparison of each LF query SN segment that passed the LFDIKEY Threshold with each LFSN\_TYPE.
- 3.12.4.31. The digraph comparison will identify the set of names to be retrieved from the database.
  - 3.12.4.31.1. See Section 3.11.4.19.4 for the digraph analysis function and formula.

- 3.12.4.31.2. The LFP will access the Hispanic Parameter Data Store to determine the LF\_DI Threshold.
- 3.12.4.31.3. For a segment to qualify for further processing, the digraph value must pass the LF\_DI Threshold found in the Hispanic Parameter Data Store.

Figure 20: Example: Digraph Filter of LFST Candidate SN Segments

LF QUERY SN: FLORENZAN	LFSN_TYPES PASSING LFDIKEY THRESHOLD	DIGRAPH SCORE	PASS LF_DI THRESHOLD: 0.57?
FLORENZAN	FLORENZAN	2*10/20 = 1.00	YES
FLORENZAN	FLORESZ	2*5/18 = 0.56	NO
FLORENZAN	LORENZ	2*5/17 = 0.59	YES

- 3.12.4.32. The LFP will assign a key (DI\_KEY) to each LFSN\_TYPE that passes the LF\_DI Threshold.
  - 3.12.4.32.1. The DI\_KEY will be the ID\_NO associated with the LFSN\_TYPE in the LFST.
  - 3.12.4.32.2. The DI\_KEY will contribute to the building of the retrieval key.
- 3.12.4.33. For a segment that passes the LF\_DI Threshold, the LFP will retain the digraph score derived from the digraph evaluation and associate it with the appropriate DI\_KEY.
- 3.12.4.34. Low Frequency Surname Segment Not in LFST
- 3.12.4.35. Add:
- 3.12.4.36. If the LF SN record add segment is not in the LFST, the LFP
  - will append the LF SN to the LFST as a LFSN\_TYPE and assign the next ID\_NO available;
  - will generate the LFDIKEYs for the new LFSN\_TYPE and will add them to the LFST with the LFSN\_TYPE;
  - will assign the ID\_NO to the LF SN segment of added record and
  - will determine if the LF SN is a variant of a HFSN\_TYPE and therefore should also be added to the HFSV Data Store.
- . 3.12.4.37. The LFP will append the LF SN segment and its LFDIKEYs to the LFST.
  - 3.12.4.37.1. The LFP will assign the next available ID\_NO to the newly entered LF SN (LFSN\_TYPE).
  - 3.12.4.37.2. The LFP will generate the LFDIKEYs to be associated with the LF SN segment (see 3.13.4.42).
  - 3.12.4.37.3. The up-to-10 keys will be added to the LFST along with the LFSN\_TYPE.

- 3.12.4.37.4. The LFP will assign the LFSN\_TYPE ID\_NO to the LF SN segment for storage with the record add.
- 3.12.4.38. The LFP will determine if a LF SN segment that was not identified as a HFSN\_VAR in the HFSV and that was not identified as a LFSN\_TYPE in the LFST is a potential variant of a HFSN\_TYPE.
  - 3.12.4.38.1. The LFP will access the High Frequency Surname Type Data Store (HFST) to determine if the LF SN segment is a digraph variant of one or more of the HFSN\_TYPEs.
    - 3.12.4.38.1.1. The LFP will perform a digraph evaluation of the LF SN and each HFSN\_TYPE. (See Section 3.11.4.19.4 for details of the procedure and formula for performing a digraph evaluation.)
    - 3.12.4.38.1.2. To qualify for addition to the HFSV as a variant of one or more HFSN\_TYPEs, the digraph value must pass a threshold, the High Frequency Surname Variant Threshold (HFSV Threshold).
    - 3.12.4.38.1.3. The LFP will access the Hispanic Parameter Data Store to determine the HFSV Threshold that the digraph value must pass for the LF SN to be appended to the HFSV Data Store.
  - 3.12.4.38.2. If the LF SN segment is determined to be a digraph variant of one or more HFSN\_TYPEs, the LFP
    - will append the LF SN to the HFSN\_TYPEs to which it is related by entering the name into the HFSN\_VAR list;
    - will assign an ID\_NO to the newly added HFSN\_VAR;
    - will assign the SET\_ID to the newly added HFSN\_VAR
       that corresponds to the SET\_ID of the HFSN\_TYPE with which the new HFSN\_VAR is associated;
    - will enter the digraph value into DI\_VAL; and
    - will store with the LF SN segment in the record add the ID\_NO of the HFSN\_VAR for each entry, the SET\_ID of each HFSN\_TYPE that is the parent of the HFSN\_VAR and the DI\_VAL for each relationship.
- 3.12.4.39. Query
- 3.12.4.40. If the LF SN query segment is not in the LFST, the LFP
  - will generate the LFDIKEYs for the new LF SN;
  - will select the related LFSN\_TYPEs through the LF selection process; and
  - will determine if the LF SN is a variant of a HFSN\_TYPE, assign appropriate keys and retain related digraph values. (See Section 3.12.4.43).

ساندان.

- 3.12.4.41. The LFP will generate the LFDIKEYs for the LF SN segment (see Section 3.12.4.44).
- 3.12.4.42. The LFP will identify LFSN\_TYPEs in the LFST that are variants of the LF. (See Section 3.12.4.11 for the identification process.)
- 3.12.4.43. The LFP will determine if a LF SN segment that was not identified as a HFSN\_VAR and that was not found in the LFST is a potential variant of a HFSN\_TYPE.
  - 3.12.4.43.1. The LFP will access the HFST Data Store and perform a digraph evaluation between the LF SN and each HFSN\_TYPE. (See Section 3.11.4.19.4 for details of the procedure and formula for performing a digraph evaluation.)
  - 3.12.4.43.2. The digraph value must pass a threshold for the LF SN to be considered a variant of a HFSN\_TYPE(s), the High Frequency Surname Variant Threshold (HFSV Threshold).
  - 3.12.4.43.3. The LFP will access the Hispanic Parameter Data Store to determine the HFSV Threshold that the digraph value must pass for the LF SN to qualify as a variant of a HFSN\_TYPE.
  - 3.12.4.43.4. If the LF SN segment passes the HFSV Threshold, the LFP will assign HFSN\_VAR Key(s) to the LF SN segment.
    - 3.12.4.43.4.1. The HFSN\_VAR Key will be the ID\_NO associated with the HFSN\_VAR that is equal to the HFSN\_TYPE.
      - 3.12.4.43.4.1.1. That is, the LF SN segment will be associated with the parent HFSN\_TYPE only.
      - 3.12.4.43.4.1.2. A LF SN may be a variant of multiple HFSN\_TYPEs and may therefore receive multiple HFSN\_VAR Keys.
    - 3.12.4.43.4.2. The calculated digraph value will be associated with each HFSN\_VAR Key.
  - 3.12.4.43.5. If, by virtue of this process, all LF SN segments in a query are set equal to HFSN\_VAR Keys, the LFP will direct the query record to the HFP (Section 3.11.) for generation of Given Name Keys, submission to the High Frequency Decision Matrix (HDM) and identification of retrieval criteria.

# 3.12.4.44. Generating LFDIKEYs

- 3.12.4.44.1. The LFDIKEY is
  - 1) a set of digraphs formed from the LF SN segment beginning with the leftmost character and
  - 2) a set of positional variants on those digraphs.

- 3.12.4.44.2. Positional information will be associated with each digraph.
- 3.12.4.44.3. Base Keys
- 3.12.4.44.4. The LFP will begin with the leftmost character and generate up to four digraph keys (Base Keys) from the (up to) five leftmost characters of the LF SN segment.
  - 3.12.4.44.4.1. The first two characters form a digraph, the second and third characters form a digraph, the third and fourth characters form a digraph and the fourth and fifth characters form a digraph.
  - 3.12.4.44.4.2. Positional information will be included: 1, 2, 3, 4, respectively: DI1, DI2, DI3, DI4.
- 3.12.4.44.5. If the LF SN segment has fewer than five characters, the LFP will generate fewer than four Base Keys, up to the number of characters in the LF SN.
- 3.12.4.44.6. Positional information will be included.
- 3.12.4.44.7. Position Keys
- 3.12.4.44.8. The LFP will generate from the Base Keys up to six additional Position Keys from the Base Keys.
  - 3.12.4.44.8.1. A maximum of ten keys (Base + Position) will be generated.
  - 3.12.4.44.8.2. The Position Keys have the same characters as the Base Keys but contain different positional information.
  - 3.12.4.44.8.3. For segments with 5 or more characters:
  - 3.12.4.44.8.4. The LFP will produce a Position Key on the first Base Key with Position 2.
  - 3.12.4.44.8.5. The LFP will produce Position Keys on the second Base Key with Position 1 and Position 3.
  - 3.12.4.44.8.6. The LFP will produce Position Keys on the third Base Key with Position 2 and Position 4.
  - 3.12.4.44.8.7. The LFP will produce a Position Key on the fourth Base Key with Position 3. No Position Key is generated for Position 5 because the maximum of 10 keys has been reached.
  - 3.12.4.44.8.8. For segments with fewer than 5 characters:
  - 3.12.4.44.8.9. The LFP will produce Position Keys in the same way as for longer LF SN segments.

- 3.12.4.44.8.9.1. No Position Key will be generated for the final Base Key with a position to the right of the final character.
- 3.12.4.44.8.9.2. The total number of LFDIKEYs will be fewer than with a longer LF SN segment.
- 3.12.4.44.8.9.3. In GOMA, the LFP will generate a total of 7 keys: the Base Keys GO1, OM2 and MA3, and the Position Keys, GO2, OM1, OM3, and MA2. (Note: No MA4 Position Key is produced for the final digraph.)

Figure 21: Example: LFDIKEYs for LF SN Segments

بداما فرزرا

LF SN SEGMENT	LFDIKEYS: BASE KEYS	LFDIKEYS: POSITION KEYS
CARRIOS	CA1 / AR2 / RR3 / RI4	CA2 / AR1 / AR3 / RR2 / RR4 / RI3
BALA	BA1/AL2/LA3	BA2/AL1/AL3/LA2

- 3.12.4.44.9. Building LF Retrieval Keys (Query)
- 3.12.4.44.10. General
- 3.12.4.44.11. Each LF SN segment has been assigned a DI\_KEY or set of DI\_KEYs.
- 3.12.4.44.12. A LF SN segment may also have been assigned one or more HFSN\_VAR Keys.
- 3.12.4.44.13. The LFP has sent queries with all HFSN\_KEYs and/or HFSN\_VAR Keys (including SN\_INIT Keys) to the HFP for further processing.
- 3.12.4.44.14. The LFP will build sets of retrieval keys for mixed frequency queries (at least one HF key and one LF SN key in the string) and for queries with all low frequency keys (all SN in the string must be DI\_KEYs).
  - 3.12.4.44.14.1. A single query may have various formats all HF, mixed and/or all-LF SN depending on the results of LF processing prior to this stage.
- 3.12.4.44.15. Mixed frequency queries will not contain SN\_INIT Keys.
  - 3.12.4.44.15.1. SN\_INIT Keys may occur with HF SN keys, in which case the record will be treated as an all-HF SN record.
  - 3.12.4.44.15.2. SN\_INIT Keys may occur with LF SN keys, in which case the record will be treated as an all-LF SN record.

- 3.12.4.44.16. Queries with Mixed Frequency (HF + LF) Surnames
- 3.12.4.44.17. Type 1:
- 3.12.4.44.18. If one SN in the query is a HF SN and has an associated HFSN\_KEY and one SN in the query record is a LF SN segment and has associated DI\_KEYs, the LFP will build a Mixed Key of the HFSN\_KEY and each DI\_KEY (and the associated DI\_VALs).
  - 3.12.4.44.18.1. The HFSN\_KEY represents a set of variants of one HFSN\_TYPE.
    - 3.12.4.44.18.1.1. GARCIA, GARCA, GARZA are all digraph variants of the HFSN\_TYPE GARCIA, which has the SET\_ID 0001.
    - 3.12.4.44.18.1.2. Record adds and queries will already have been assigned the HFSN\_KEY through the HFP.
  - 3.12.4.44.18.2. The DI\_KEY represents a *single* low frequency surname type that has qualified through the LF SN selection process.

Figure 22: Example: Building Mixed HF/LF SN Retrieval Keys with HFSN\_KEY and DI\_KEYs

QUERY NAME: GARCIA FLORENZAN	HFSN_KEY and (LF) DI_KEY
GARCIA (HF)	GARCIA → 001
FLORENZAN (LF)	FLORENZAN → 000189
GARCIA (HF)	GARCIA → 001
LORENZ (LF)	LORENZ → 000412

## 3.12.4.44.19. Type 2:

- 3.12.4.44.20. If one SN in the query record is a HF SN and has an associated HFSN\_VAR Key (generated by the LFP) and one SN in the query record is a LF SN segment with associated DI\_KEY(s), the LFP will build a Mixed Key of the HFSN\_VAR Key and the DI\_KEY for each qualifying LFSN\_TYPE.
  - 3.12.4.44.20.1. The HFSN\_VAR represents a single HFSN\_TYPE and not a set of variants.
    - 3.12.4.44.20.1.1. Record adds and queries will already have been assigned the HFSN\_VAR Key through the LFP.

3.12.4.44.20.2. The DI\_KEY represents a *single* low frequency surname type that has qualified through the LF SN selection process.

Figure 23: Example: Building Mixed HF/LF SN Retrieval Keys with HFSN\_VAR Keys and DI\_KEYs

QUERY NAME: GARCIA FLORENZAN	HFSN_VAR and (LF) DI_KEY
BOMEZ (LF → HFSN_VAR)	BOMEZ → 016978
FLORENZAN (LF)	FLORENZAN → 000189
BOMEZ (LF → HFSN_VAR)	BOMEZ → 016978
LORENZ (LF)	LORENZ → 000412.

- 3.12.4.44.21. It is likely that there will be multiple DI\_KEYs for each LF SN segment, resulting in multiple Mixed Keys.
- 3.12.4.44.22. Once the Mixed SN Keys have been generated (and. DI\_VALs associated with the appropriate keys), the LFP will send any query that contains mixed HF and LF Keys to the HFP (Section 3.11.4.5) for Given Name processing and identification of retrieval criteria from the Hispanic Decision Matrix.
- 3.12.4.44.23. Queries with All Low Frequency (LF + LF)
  Surnames
- 3.12.4.44.24. The LFP will identify the LF Keys associated with query formats made up solely of LF SN segments (or a LF SN segment and SN\_INIT Key(s)).
  - 3.12.4.44.24.1. The LFP has qualified one or more LF SN segments from the LFST as variants of each LF query SN.
  - 3.12.4.44.24.2. Each qualifying LF segment has been assigned a LF Key, the DI\_KEY, and has an associated digraph value, DI\_VAL.

Figure 24: Example: Low Frequency DI\_KEYs and Associated Digraph Values

QUERY NAME: TOREAT FLORENZAN	LFST ID_NO	DI_KEYs + DI_VAL
TOREAT	TOREAT → 000714	000714 (1.00)
THORET	THORET → 000652	000652 (0.57)
FLORENZAN	FLORENZAN → 000189	000189 (1.00)
FLORESZ	FLORESZ → 000232	000232 (0.56)
LORENZ	LORENZ → 000412	000412 (0.59)

3.12.4.44.25. The LFP will direct a query record with all DI\_KEYs and their digraph values (or DI\_KEYs and SN\_INIT Keys) to the Hispanic Search Engine for retrieval of database records.

ente.

#### 3.12.5. Subordinates

None.

## 3.13. HISPANIC SEARCH ENGINE MODULE DECOMPOSITION

#### 3.13.1. Identification

This module is known as the Hispanic Search Engine (HSE).

## 3.13.2. Type

بالماؤن

- 3.13.2.1. The HSE is a function that applies to queries only.
- 3.13.2.2. The HSE will accept name keys and retrieval criteria from the HFP and the LFP.
  - 3.13.2.3. The module must follow the HFP and LFP.

## 3.13.3. Purpose

The HSE will retrieve records from the VLDB based on criteria identified by the High Frequency Processor and the Low Frequency Processor. These criteria will delimit the set of records that can qualify for retrieval. The system must be sure that the criteria have all been identified and can be associated with database records (whether through database design and/or key generation).

### 3.13.4. Function

- 3.13.5. HNA-E will not handle records with Last Name Unknown (LNU).
- 3.13.6. The HSE will permit First Name Unknown (FNU).
  - 3.13.6.1. The processing of FNU will supersede other GN restrictions.
  - 3.13.6.2. The HSE will retrieve any database GN when FNU occurs in the query.
  - 3.13.6.3. The HSE will retrieve any FNU in the database for any query GN.

## 3.13.7. High Frequency Retrieval

- 3.13.7.1. High frequency retrieval will include records with HFSN\_KEYs, HFSN\_VAR Keys and SN\_INIT Keys that occur with the HF SN keys.
  - 3.13.7.1.1. The SN\_INIT Key will result in the retrieval of records that begin with or are equal to the variant initials identified by the SN\_INIT Key.
  - 3.13.7.1.2. The SN\_INIT Key is stored with each SN segment.
  - 3.13.7.1.3. All HF retrieval restrictions apply to the SN\_INIT Key, as if it were a HF segment *except* that
    - 3.13.7.1.3.1. If the SN\_INIT Key is the only key in the format, the HSE will not undertake a database search.
  - 3.13.7.1.4. No further, separate detailing of the SN\_INIT Key is given.

3.13.7.2. High frequency retrieval will include mixed HF and LF SN Keys but with no SN\_INIT Keys.

## 3.13.8. All HFSN\_KEYs (or SN\_INIT Key)

- 3.13.9. For queries with all HFSN\_KEYs, the HSE will retrieve records from the database records that
  - contain the appropriate SN format (position, more/fewer segments, different segments) as specified in the HDM,
  - contain the appropriate HFSN\_KEYs,
  - meet all the criteria identified in the HDM and
  - meet the GN restrictions.
- 3.13.10. The HFSN\_KEY will result in retrieval of the HFSN\_TYPE and all its variants.
  - 3.13.10.1. The HSE will further restrict the retrieval to records that match at least one key of the GN.
    - 3.13.10.1.1. If the query has produced only HFGN\_KEYs, only records that have at least one of the HFGN\_KEYs will be retrieved.
    - 3.13.10.1.2. If the query has produced mixed HFGN\_KEYs and GN\_INIT Keys, the HSE will retrieve records that match at least one of the HFGN\_KEY or one of the GN\_INIT Keys.
    - 3.13.10.1.3. If the query has produced only GN\_INIT Keys, the HSE will retrieve records that match at least one of the GN\_INIT Keys.

## 3.13.11. HFSN\_KEY and/or HFSN\_VAR Keys (or SN\_INIT Key)

- 3.13.12. For queries with mixed HFSN\_KEYs and HFSN\_VAR Keys and queries with all HFSN\_VAR Keys, the HSE will retrieve records from the database records that
  - contain the appropriate HFSN\_KEYs and/or HFSN\_VAR Keys,

HNA-E Language Analysis Systems, Inc.

. المانية

47

- contain the appropriate SN format (position, more/fewer segments, different segments) as specified in the HDM,
- · meet all the criteria identified in the HDM and
- meet the GN restrictions.
- 3.13.13. The HFSN\_VAR Key will retrieve a *single* HFSN\_TYPE and not the set of variants associated with the HFSN\_TYPE (e.g., the name LOPEZ but not all its variants; the variants will be retrieved by the LFP).
  - 3.13.13.1. The HSE will further restrict the retrieval to records that match at least one key of the GN.
    - 3.13.13.1.1. If the query has produced only HFGN\_KEYs, only records that have at least one of the HFGN\_KEYs will be retrieved.
    - 3.13.13.1.2. If the query has produced mixed HFGN\_KEYs and GN\_INIT Keys, the HSE will retrieve records that match at least one of the HFGN\_KEY or the GN\_INIT Keys.
    - 3.13.13.1.3. If the query has produced only GN\_INIT Keys, the HSE will retrieve records that match at least one of the GN\_INIT Keys.

Language Analysis Systems, Inc.

- 3.13.14. Mixed HFSN\_KEY and/or HFSN\_VAR Keys and LF DI\_KEYs (no SN\_INIT Key)
- 3.13.15. For queries with mixed HFSN\_KEYs/HFSN\_VAR Keys and LF DI\_KEYs, the HSE will retrieve records from the database records that
  - contain the appropriate HFSN\_KEYs/HFSN\_VAR Keys and DI\_KEYs,
  - contain the appropriate SN format (position, more/fewer segments, different segments) as retrieved from the HDM,
  - meet all the criteria identified in the HDM and
  - · meet the GN restrictions.
- 3.13.16. The LFP generated (multiple) query formats that contain a HF Key and a DI\_KEY.
  - 3.13.16.1. The DI\_KEY will retrieve an exact match on a single LFSN\_TYPE.
- 3.13.16.2. Each HFSN\_KEY or HFSN\_VAR Key may participate in query formats with several different DI\_KEYs that were identified as variants by the LFP.
  - 3.13.16.3. Each query format will serve as a different query.
  - 3.13.17. The HSE will further restrict the retrieval to records that match at least one key of the GN.
    - 3.13.17.1: If the query has produced only HFGN\_KEYs, only records that have at least one of the HFGN\_KEYs will be retrieved.
    - 3.13.17.2. If the query has produced mixed HFGN\_KEYs and GN\_INIT Keys, the HSE will retrieve records that match at least one of the HFGN\_KEY or the GN\_INIT Keys.
    - 3.13.17.3. If the query has produced only GN\_INIT Keys, the HSE will retrieve records that match at least one of the GN\_INIT Keys.

Figure 28: Example: Record Matching Criteria: Mixed HFSN\_KEYs/HFSN\_VAR Keys and LF DI\_KEYs

Keys and LF D1_I		<del></del>	T	T	an-man-
QUERY #1	THORET	SLOPEZ	JOSSE	CARLOS	CRITERIA
HFSN_KEY			<u>.l</u>

HNA-E Language Analysis Systems, Inc.

4.6

- 3.13.18. The HSE will not retrieve database records that have already been retrieved with another key.
- 3.13.19. The HSE will retrieve the database record ID; the Dual-SN Formats; keys, their segment position and their related DI\_VALs; Record Gender; and TAQ tags.

### 3.13.20. Low Frequency Retrieval

- 3.13.21. The HSE will retrieve records from the database that contain one or both of the query DI\_KEYs in any SN position in the database record.
  - 3.13.21.1. The HSE will retrieve records that contain the DI\_KEYs within a specified YOB Range for a Refusal Code Level.
  - 3.13.21.2. The HSE will access the RLYOB Data Store to determine the Refusal Code Level and associated Year-of-Birth Range that will apply.
  - 3.13.21.3. The HSE will retrieve all records from the database with
    - both DI\_KEYs (or one DI\_KEY and one SN\_INIT Key) in either position and RLYOB restriction;
    - one of the DI\_KEYs alone and RLYOB restriction; and
    - one DI\_KEY in either position, if the Year-of-Birth Range is YOB2 and the Refusal Code Level is RL1 (i.e., 00 or Type 1 Serious).
- 3.13.22. The HSE will retrieve the database record; the record ID; the Dual-SN Formats; keys, their segment position and their related DI\_VALs; Record Gender; and TAQ tags.
- 3.13.23. The HSE will not retrieve a record that has already been retrieved using other access methods (i.e., Mixed Frequency SN or HF names).
- 3.13.24. All records retrieved from the database will be sent to the Hispanic Filter and Sorter.

## 3.14. HISPANIC FILTER AND SORTER MODULE DECOMPOSITION

#### 3.14.1. Identification

This module is known as the Hispanic Filter and Sorter (HFS).

#### 3.14.2. Type

- 3.14.2.1. The HFS is a module that accepts database records retrieved by the HSE.
- 3.14.2.2. The HFS compares each database record to the query record to determine if it qualifies for return to the user.
- 3.14.2.3. The HFS is constituted of two subordinate functions: the Hispanic Filter and the Hispanic Sorter.
- 3.14.2.4. The HFS must follow the Hispanic Search Engine (HSE).

## 3.14.3. Purpose

anti.

- 3.14.3.1. The set of database records that the HSE will retrieve will be a set of records delimited by quite narrow retrieval criteria. The database records will have a digraph value associated with most SN segments and with many GN segments. However, the relative value of the database records to the query record will not be clear. The HFS will, therefore, evaluate each of the records retrieved for its proximity to a query record, will retain those that pass a pre-established threshold and will sort the resultant candidate list.
- 3.14.3.2. The filtering process will take into account a number of factors that play a role in determining the relative value of Hispanic *names*.
- 3.14.3.3. The filtering process will take into account factors that aid in the determination of the relative value of a Hispanic *records*.

#### 3.14.4. Function

The HFS will first compare and qualify the query name and database record name to determine a surname value (SN\_VAL), will then evaluate and qualify the query name and database record to determine a given name value (GN\_VAL) and will generate a composite score for the database records that qualified on the basis of name evaluation by factoring in values for Date-of-Birth, Refusal Level and Country of Birth.

The first comparison will be to identify an exact record match. All other comparison will be between the Dual-SN Format of the query and database record (for records with more than two surnames).

HNA-E Language Analysis Systems, Inc. 52

- 3.14.4.1. Filter Function of the HFS
- 3.14.4.2. General

2.304.

- 3.14.4.3. The Hispanic Filter and Sorter (HFS) will accept the candidate database records retrieved by the HSE.
- 3.14.4.4. The HFS will first determine if the query record and database record match exactly.
  - 3.14.4.4.1. The HFS will compare the base format of the query and database record; i.e., no derived format.
  - 3.14.4.4.2. The name (both SN and GN), Date-of-Birth and Country-of-Birth must match exactly.
  - 3.14.4.4.3. If the query and database records match exactly, the HFS will tag the record as an exact match and send the record directly to the Sorter Function of the HFS.
- 3.14.4.5. The HFS will calculate name scores for each candidate database record as it compares to the query record.
  - 3.14.4.5.1. The HFS will use the derived formats as the basis of record comparison.
  - 3.14.4.5.2. A score for the SN, the SN\_VAL, will be calculated.
  - 3.14.4.5.3. A score for the GN, the GN\_VAL, will be calculated.
    - 3.14.4.5.3.1. The HFS will adjust the digraph value retrieved with the database record by multiplying that value by factors assigned to several parameters.
    - 3.14.4.5.3.2. Factors (see Section 4.13) that contribute to the determination and evaluation of the name score (SN\_VAL and GN\_VAL) include
    - SNTHR
    - GNTHR
    - ASVAL
    - AGVAL
    - OPSVAL
    - OPGVAL
    - INITSN
    - INITGN
    - TAQASN
    - TAQAGN
    - TAQXSN
    - TAQXGN
    - RGNDR

HNA-E Language Analysis Systems, Inc. 53

3.14.4.5.3.3. To be included in the final candidate list, the score of the SN and the score of the GN must each pass predetermined SN and GN threshold levels (SNTHR and GNTHR).

#### 3.14.4.6. Surname Evaluation

- 3.14.4.7. A candidate record must pass a SN evaluation before it will be submitted to a GN evaluation.
- 3.14.4.8. No record with Last Name Unknown (LNU) will be handled by HNA-E.
- 3.14.4.9. The SN evaluation will be performed on the dervied formats (including the Dual-SN Formats) associated with the query and database records

#### 3.14.4.10. High Frequency SN Keys (HFSN\_KEYs or HFSN\_VAR Keys)

- 3.14.4.10.1. The HFS will compare the keys of the query and database and assign the DI\_VAL retrieved with the database record to the SN Comparands with matching keys.
  - 3.14.4.10.1.1. Only one assignment of DI\_VAL can be made for a match.
  - 3.14.4.10.1.2. If the query is GARCIA GOMEZ and the database record is GARCIA GARCIA, the HFS will assign the DI\_VAL to one GARCIA match only.
- 3.14.4.10.2. If the SN Keys do not match, the HFS will perform a digraph match of the segments with no assigned value (LOPEZ and GOMEZ in Figure 29) and will assign the digraph score to the DI\_VAL.

Figure 29: Example: Database Records with HFSN\_KEYs to be Evaluated by HFS

	SN#1	HFSN KEY	DI_VAL	SN#2	HFSN_KEY	DI_VAL
QUERY	GARCIA	0001		GOMEZ	0010	
DATABASE RECORDS	GARCIA	0001	1.00	BOMEZ	0010	0.67
	BARCIA	0001	0.71	GAMEZ	0010	0.67
	LOPEZ	0004	0.17	GARCIA	0001	1.00

## 3.14.4.11. Low Frequency SN Keys (DI\_KEYs)

- 3.14.4.11.1. The HFS will assign the DI\_VAL associated with the DI\_KEY to matching database and query DI\_KEYs.
  - 3.14.4.11.1.1. Only one assignment of DI\_VAL can be made for a match.

- 3.14.4.11.1.2. If the query is THORET FLORENZAN and the database record is THORET THORET, the HFS will assign the DI\_VAL to one THORET match only.
- 3.14.4.12. If the SN Keys do not match, the HFS will perform a digraph match of the segments with no assigned value (LOPEZ and GARCIA in Figure 30) and will assign the digraph score to the DI\_VAL.
  - 3.14.4.12.1. If there is more than one pair that does not have an assigned digraph value, the HFS will perform a digraph evaluation for each of the pairs. (See Section 3.14.4.16 for details of the digraph assignment.)
  - 3.14.4.12.2. Each value will be submitted to parameter evaluation.
  - 3.14.4.12.3. After all parameters have been applied, the HFS will choose the highest score for each pair. (See Section 3.14:4.17)

Figure 30: Example: Database Records with LF SN (Mixed or all LF Keys) to be Evaluated by HFS

	SN#1	HFSN_KEY/ DI-KEY	DI_VAL	SN#2	HFSN_KEY/ DI_KEY	DI_VAL
QUERY	GARCIA	0001		THORET	000652	
DATABASE RECORDS	GARCIA	0001	1.00	THORET	- 000652	1.00
	THORET	000652	1.00	BARCIA	0001	0.71
	LOPEZ	0004	0.00	THORET	000652	1.00

- 3.14.4.13. The HFS will adjust the DI\_VAL of each segment according to parameter values in the Hispanic Parameter Data Store (see Section 4.13 for details).
  - 3.14.4.13.1. The HFS will determine if the appropriate parameter conditions obtain.
  - 3.14.4.13.2. If the appropriate conditions are present, the DI\_VAL will be multiplied by the value assigned to the parameter and the DI\_VAL will be lowered.
  - 3.14.4.13.3. Parameter Conditions
  - 3.14.4.13.4. INITSN: Initial
    - 3.14.4.13.4.1. Definition 1: The SN segment is a single character in both comparands and the character matches exactly.
    - 3.14.4.13.4.2. Action: The HFS will make no change.
    - 3.14.4.13.4.3. Definition 2: A SN segment is a single character and its SN\_INIT Key matches the SN\_INIT Key of the other comparand.

- 3.14.4.13.4.4. Action: Assign the INITSN value to the comparison value (i.e., do not calculate the DI\_VAL). The initial may be subjected to any following actions (e.g., out-of-place segment).
- 3.14.4.13.4.5. Definition 3: A SN segment is a single character and the SN\_INIT Keys of the comparands do not match.
- 3.14.4.13.4.6. Action: Assign the INITNM value to the comparison value (i.e., do not calculate the DI\_VAL). The initial may be subjected to any following actions (e.g., out-of-place segment).
- 3.14.4.13.5. OPSVAL: Out-of-Place Surname Value
  - 3.14.4.13.5.1. Definition: A SN segment that is not in the same relative position in the SN string in both the database and query records.
  - 3.14.4.13.5.2. Action: Multiply the DI\_VAL by the OPSVAL.
- 3.14.4.13.6. ASVAL: Anchor Surname Value
  - 3.14.4.13.6.1. Definition: For database records that contain two SN segments, the database SN segments are in the correct position relative to the query SN segments.
  - 3.14.4.13.6.2. Action: Multiply the DI\_VAL of the second (rightmost) segment by the ASVAL.

Figure 31: Example 1: SN Parameter Evaluation: OPSN Applies

	GARCIA	GOMEZ
BOMEZ		0.67 * 0.65 = 0.44
GARCIA	1.00 * 0.65 = 0.65	

Figure 32: Example 2: SN Parameter Evaluation: OPSN Applies

	Tigure 32. Example	D. DITTUIGHTOLDE	iluation. Of biv rippine
į		GARCIA	GOMEZ
!	GAMEZ		0.67 * 0.65 = 0.44

Figure 33: Example 3: SN Parameter Evaluation: ASVAL Applies

·	GARCIA	GOMEZ
GARZA	0.62	
GOMEZ		1.00 * 0.65 = 0.65

### 3.14.4.13.7. TAQ Filter

3.14.4.13.8. All TAQ tags (ID\_NO, disposition, TAQ\_TYPE and associated SN stem) will be retrieved with the database record.

- 3.14.4.13.9. The HFS will evaluate any TAQs associated with the SN segments being evaluated, except Stranded Prefixes (see Section 3.5.4.2.7.3).
  - 3.14.4.13.9.1. A Stranded Prefix will not play a role in the record comparison.
- 3.14.4.13.10. Single TAQs
- 3.14.4.13.11. Missing TAQs
- 3.14.4.13.12. TAQASN: Absent TAQ Value
  - 3.14.4.13.12.1. Definition 1: One of the two comparands (query/database SN segment) has a TAQ tag, the other does not.
  - 3.14.4.13.12.2. Definition 2: Both comparands (query/database SN segments) have a single TAQ tag, one is a TAQ DELETE, the other a TAQ DISREGARD.
  - 3.14.4.13.12.3. Action: Multiply the DI\_VAL by the TAQASN value.

Figure 34: Example: TAQ DISREGARD (DE) and No TAQ

	DE VARGAS
VARGAS	1.00 * 0.90 = 0.90

Figure 35: Example: TAQ DISREGARD (DE) and TAQ DELETE (DR)

	DE VARGAS
DR VARGAS	1.00 * 0.90 = 0.90

3.14.4.13.13. TAQ DELETE

3.14.4.13.14. TAQXSN: Deleted TAQ Value

- 3.14.4.13.14.1. Definition: Both SN comparands have a single TAQ DELETE tag.
- 3.14.4.13.14.2. Action:
- 3.14.4.13.14.3. If the TAQ DELETE tags refer to the same TAQ segment, the DI\_VAL will be unchanged.
- 3.14.4.13.14.4. If the TAQ DELETE tags refer to different TAQ DELETE segments, multiply the DI\_VAL by the TAQXSN value.

Figure 36: Example: Same TAQ DELETE (DR)

	DR VARGAS
DR VARGAS	1.00

Figure 37: Example: Different TAQ DELETEs (DR and SR)

	SR VARGAS
DR VARGAS	1.00 * 0.850 = 0.85

### 3.14.4.13.15. TAQ DISREGARD

- 3.14.4.13.15.1. Definition: The HFS will access the TAQ Filter
  Data Store (TF) to process records that both contain SN
  TAQ segments that have been tagged as DISREGARD.
- 3.14.4.13.15.2. Action 1: The HFS will assign TAQDIS#1 to the TAQ DISREGARD segment for the database SN segment and TAQDIS#2 to the TAQ DISREGARD segment for the query SN segment.
- 3.14.4.13.15.3. Action 2: If the two TAQ DISREGARD segments match, the DI\_VAL will remain unchanged.
- 3.14.4.13.15.4. Action 3: If the two TAQ DISREGARD segments do not match, the HFS will identify the TF\_VALUE for the pair in the TF.
  - 3.14.4.13.15.4.1. The HFS will multiply the DI\_VAL by the TF\_VALUE for the pair.

Figure 38: Example: Different TAQ DISREGARDs (DE and LA)

	DE PENA
LA PENA	1.00 * 0.75 = 0.75

### 3.14.4.13.16. Multipart TAQs

- 3.14.4.13.16.1. Definition: If at least one SN comparand has multipart TAQ tags (they may be all DISREGARD, all DELETE, or mixed DISREGARD/DELETE), the HFS will perform the following analyses.
- 3.14.4.13.16.2. Action: If all TAQs match, HFS will make no change in the DI\_VAL.

## 3.14.4.13.16.3. TAQ DELETEs

- 3.14.4.13.16.3.1. Definition: All DELETE tags
- 3.14.4.13.16.3.2. Action 1: If any DELETE TAQ matches, the HFS applies no change.
- 3.14.4.13.16.3.3. Action 2: If no DELETE TAQs match, multiply the DI\_VAL by the TAQXSN Value.

Figure 39: Example: Multiple TAQ DELETEs with Some Match

HNA-E Language Analysis Systems, Inc.

	REV DR VARGAS
REV VARGAS	1.00

Figure 40: Example: Multiple TAO DELETEs with No Match

1.5aic to. Example. Mainple II	Q DEBETES WITH THE INTEREST
· ·	GENERAL DR VARGAS
REV SR VARGAS	1.00 * 0.85 = 0.85

## 3.14.4.13.16.4. TAQ DISREGARDs

3.14.4.13.16.4.1. Definition: All DISREGARD tags

3.14.4.13.16.4.2. Action 1: If any TAQ DISREGARD segment matches, the HFS will make no change in the DI\_VAL.

3.14.4.13.16.4.3. Action 2: If no TAQ DISREGARD segments match, the HFS will identify the highest match value from the TF (TF\_VALUE) and multiply that by the DI\_VAL.

Figure 41: Example: Multiple TAQ DISREGARDs with Matching TAQ Segment (DE LAS/DE LOS)

	DE LAS LUNAS
DE LOS LUNAS	1.00

Figure 42: Example: Multiple TAQ DISREGARDs with No Matching TAQ Segment (DE SANTA/LA)

		DE SANTA MARIA
Ì	LA MARIA	1.00 * 0.75 = 0.75

## 3.14.4.13.16.5. TAQ DISREGARD and DELETEs

3.14.4.13.16.5.1. Definition: Mixed DISREGARD/DELETE tags

- 3.14.4.13.16.5.2. Action 1: If DISREGARD segments are present in both comparands and there is any match among the DISREGARD segments, the HFS will make no change in the DI\_VAL.
- 3.14.4.13.16.5.3. Action 2: If DISREGARD segments are present in both comparands and there is no match among the DISREGARD segments, the HFS will determine the highest match value from the TF for any DISREGARD tags and multiply the DI\_VAL by that value. (That is, ignore any DELETE tags.)

- 3.14.4.13.16.5.4. Action 3: If a DISREGARD segment is in one comparand and not the other and the two comparands have at least one DELETE tag that matches, the HFS will make no change in the DI\_VAL.
- 3.14.4.13.16.5.5. Action 4: If a DISREGARD segment is in one comparand and not the other and the two comparands have DELETE tags that do not match, multiply the DI\_VAL by the TAQXSN.

Figure 43: Example: Multiple TAQs, DISREGARDs (DE/LOS)

The Co.	SR DE VARGAS
DR LOS VARGAS	1.00* 0.75 = 0.75

m-15.

Figure 44: Example: Multiple TAQs, DELETEs (DRA/DR)

	DRA DE VARGAS
DR VARGAS	1.00 * 0.85 = 0.85

- 3.14.4.14. After all parameters have been applied, the HFS will calculate the SN\_VAL.
  - 3.14.4.14.1. The HFS will choose the highest value for the row and column for any SN segments that have more than one digraph value assigned to them.
  - 3.14.4.14.2. The HFS will sum the DI\_VALs of all SN segments and will divide by the number of DI\_VALs.

Figure 45: Example 1: Filter Evaluation

	GARCIA	GARCIA GOMEZ	
BOMEZ		0.67 * 0.65 = 0.44	
GARCIA	1.00 * 0.65 = 0.65		

Figure 46: Example 2: Filter Evaluation

	GARCIA	GOMEZ
GAMEZ		0.67 * 0.65 = 0.44

Figure 47: Example 3: Filter Evaluation

	GARCIA	GOMEZ
GARZA	0.62	
GOMEZ		1.00 * 0.65 = 0.65

3.14.4.14.3. In Figure 45, 0.44 + 0.65 / 2 = 0.55

3.14.4.14.4. In Figure 46, 0.44 / 1 = 0.44

3.14.4.14.5. In Figure 47, 0.62 + 0.65 / 2 = 0.64

HNA-E Language Analysis Systems, Inc.

- 3.14.4.15. The HFS will compare the SN\_VAL to the SNTHR.
  - 3.14.4.15.1. The SN\_VAL must be equal to or greater than the SNTHR.
  - 3.14.4.15.2. If the SNTHR were 0.60, only Example 3 above would pass.
  - 3.14.4.15.3. The record must pass the SNTHR to qualify for Given Name Evaluation.

### 3.14.4.16. Given Name Evaluation

- 3.14.4.16.1. The HFS will evaluate the GN in a similar way to the SN evaluation.
- 3.14.4.16.2. The HFS will assign a DI\_VAL of 1.00 to any match with FNU.
- 3.14.4.16.3. The GN format will permit more than two GN segments to be evaluated.
  - 3.14.4.16.3.1. If the segment pair has a matching HFGN\_KEY, the digraph value (DI\_VAL) retrieved with that key will be assigned to the pair being evaluated.
  - 3.14.4.16.3.2. For any segment pair that does not have a HFGN\_KEY and associated DI\_VAL, the DI\_VAL will be calculated. (See Section 3.11.4.19.4 for digraph evaluation.)
  - 3.14.4.16.3.3. The HFS will not calculate a digraph value for a GN\_INIT Key value or GN initial.
    - 3.14.4.16.3.3.1. The HFS will calculate the digraph relationship for all segments that have not been assigned a DI\_VAL.
    - 3.14.4.16.3.3.2. The HFS will not compare names that have a DI\_VAL assigned.

Figure 48: Example: GN Digraph Evaluation

1	MARIA	LORNA	SILVIA	CATERINA
CATHERINA				0.74
				(HFGN_KEY)
MARIA	1.00 (HFGN_KEY)		, .	
LARA		0.36	. 0.08	

MILDRED	0.00	0.07	

- 3.14.4.16.4. The DI\_VAL of each GN segment will be adjusted by several GN parameters.
- 3.14.4.16.5. INITGN: Given Name Initial
  - 3.14.4.16.5.1. Definition 1: The GN segment is a single character in both comparands and the character matches exactly.
  - 3.14.4.16.5.2. Action: The HFS will make no change.
  - 3.14.4.16.5.3. Definition 2: A GN segment is a single character and its GN\_INIT Key matches the GN\_INIT Key of the other comparand.
  - 3.14.4.16.5.4. Action: Assign the INITGN value to the comparison value (i.e., do not calculate the DI\_VAL). The initial may be subjected to any following actions (e.g., out-of-place segment).
  - 3.14.4.16.5.5. Definition 3: A GN segment is a single character and the GN\_INIT Keys of the comparands do not match.
  - 3.14.4.16.5.6. Action: Assign the INITNM value to the comparison value (i.e., do not calculate the DI\_VAL). The initial may be subjected to any following actions (e.g., out-of-place segment).
- 3.14.4.16.6. OPGVAL: Out-of-Place Given Name Value
  - 3.14.4.16.6.1. Definition: A GN segment that is not in the same relative position in the GN string in both the database and query records.
  - 3.14.4.16.6.2. Action: Multiply the DI\_VAL by the OPGVAL.
- 3.14.4.16.7. AGVAL: Anchor Given Name Value
  - 3.14.4.16.7.1. Definition: For database records that contain two or more GN segments, the database SN segments are in the correct position relative to the query SN segments.
  - 3.14.4.16.7.2. Action: Multiply the DI\_VAL of the GN segments to the right of the first (leftmost segment) by the AGVAL.

Figure 49: Example 1: GN Parameter Evaluation: OPGN Applies

	MARIA	CATHERINA
KATHERINA		0.90 * 0.65 = 0.59
MARIA	1.00 * 0.65 = 0.65	

Figure 50: Example 2: GN Parameter Evaluation: OPGN Applies

	JOSE	BARTOLOMEO
BARTO		0.71 * 0.65 = 0.46

Figure 51: Example 3: GN Parameter Evaluation: AGVAL Applies

	JUAN	MARIO
JUANA	0.73	
MARIA		0.83 * 0.65 = 0.54

Figure 52: Example 4: Given Name Parameter Evaluation

	MARIA	LARA	MILDRED	CATERINA
CATHERINA				0.74*0.65 = 0.48
	<u> </u>			(OPGVAL)
MARIA	1.00*0.65 = 0.65 (OPGVAL)			
	(OFGVAL)			ļ <u> </u>
LORNA	ļ.	0.36*0.65 = 0.23	0.08*0.65 = 0.05	
		(OPGVAL)	(OPGVAL)	
SILVIA		0.00*0.65 = 0.00	0.07*0.65 = 0.05	
•	•	(OPGVAL)	(OPGVAL)	

- 3.14.4.16.8. TAQ Evaluation will proceed as with the SN, mutatis mutandi (See Section 3.14.4.13.7).
- 3.14.4.17. After all GN evaluations have been performed, the HFS will choose the highest score for each GN segment that has multiple DI\_VALs (i.e., those for which no DI\_VAL was retrieved with the key).
  - 3.14.4.17.1. The highest score for **both** the row and column must be
  - 3.14.4.17.2. Only one score per row and column is permitted.
  - 3.14.4.17.3. If two scores are equal, only one is chosen.
  - 3.14.4.17.4. In the example above, the higher score for LORNA is on the match with LARA (0.23); for SILVIA, MILDRED (0.05).
    - 3.14.4.17.4.1. Note that MILDRED scores are equal, but the row for LORNA has already been chosen.
    - 3.14.4.17.4.2. Only one value can be chosen for each row and column.
- 3.14.4.18. The HFS will sum all DI\_VALs from the comparison matrix and will divide by the number of DI\_VALs to produce the GN score.
  - 3.14.4.18.1. In Example 1, 0.59 + 0.65/2 = 0.62
  - 3.14.4.18.2. In Example 2, 0.46/1 = 0.46
  - 3.14.4.18.3. In Example 3, 0.73 + 0.54/2 = 0.64
  - 3.14.4.18.4. In Example 4, 0.48 + 0.65 + 0.23 + 0.05/4 = 0.33

- 3.14.4.19. The HFS will further evaluate the Given Name by comparing the record gender of the two comparands.
  - 3.14.4.19.1. If the record genders match, no action will take place.
  - 3.14.4.19.2. If the record genders do not match, the HFS will apply the RGNDR value to the GN score.
    - 3.14.4.19.2.1. The HFS will access the TF to determine the RGNDR Value.
    - 3.14.4.19.2.2. The HFS will multiply the GN score by the RGNDR value.
- 3.14.4.20. The value resulting from the full GN evaluation will be the GN\_VAL.
- 3.14.4.21. The HFS will compare the GN\_VAL to the GNTHR.
  - 3.14.4.21.1. The GN\_VAL must be equal to or greater than the GNTHR.
  - 3.14.4.21.2. The GN\_VAL must pass the GNTHR for the record to qualify for calculation of the Composite Score.
- 3.14.4.22. Composite Score
- 3.14.4.23. The HFS will develop a composite score for two comparands that will reflect the proximity of the query and database *records*.
- 3.14.4.24. The Composite Score will be used to rank order the records being evaluated.
- 3.14.4.25. The Name is one component of the Composite Score; others are the Refusal Level, Date-of-Birth and Country of Birth.
  - 3.14.4.25.1. The HFS will adjust the GN\_VAL and the SN\_VAL by factors that reflect the proximity of the Refusal Level, Date-of-Birth and Country of Birth.
  - 3.14.4.25.2. The GN\_VAL and SN\_VAL will be multiplied by RL, YOB and COB factors.

HNA-E Language Analysis Systems, Inc.

64

#### 3.14.4.26. Refusal Level Factor

- 3.14.4.27. The HFS will access the Refusal Code Level Data Store to determine the Refusal Level Category of the Refusal Code.
- 3.14.4.28. The HFS will access the Hispanic Parameter Data Store to find the PARM\_VAL associated with the Refusal Level (RL#).

#### 3.14.4.29. Date-of-Birth Factor

بالشوند.

50.50

- 3.14.4.30. The HFS will access the Year-of-Birth Range Data Store to determine the YOB Category, YOB#, of the Dates-of-Birth of the comparands. The highest value is applied to the relationship.
- 3.14.4.31. The HFS will access the Hispanic Parameter Data Store to find the PARM\_VAL associated with the YOB Category (YOB#).

#### 3.14.4.32. Country-of-Birth Factor

- 3.14.4.33. The HFS will access the Hispanic Country-of-Birth Category Data Store (HCOB) to determine the COB Category, COB#.
  - 3.14.4.33.1. The HFS will identify the COB#.
  - 3.14.4.33.2. The HFS will access the Hispanic Parameter Data Store to find the PARM\_VAL associated with the Country-of-Birth Category (COB#).

# 3.14.4.34. Calculating the Composite Score

- 3.14.4.35. The HFS will calculate a Composite Score by multiplying the SN\_VAL by the GN\_VAL by the RL# PARM\_VAL by the YOB# PARM\_VAL by the COB# PARM\_VAL.
- 3.14.4.36. Final Sort Function of the HFS
- 3.14.4.37. The HFS will order the final candidate list.
- 3.14.4.38. The HFS will place at the top of the candidate list all records that have been tagged as exact matches.
- 3.14.4.39. The HFS will then rank order in descending order of Composite Score all records for which a Composite Score has been calculated.
  - 3.14.4.39.1. The goal of the final sort is to place exact record matches on the top and to rank order the remaining records by the degree of contribution that each data element (SN, GN, DOB, COB, Refusal Code Level (RL)) makes to the overall record value.
  - 3.14.4.39.2. Further details of the sort will be derived from extensive discussion about the business requirements.
  - 3.14.4.39.3. Because the scores from the various pipes may not have been calculated in the same way, a method for evaluating the relative value of candidate records will have to be devised.

HNA-E Language Analysis Systems, Inc.

# 3.14.4.40. Internal Sort Order

- 3.14.4.40.1. There may be cases in which the sorting criteria are met equally by more than 1 record.
- 3.14.4.40.2. Where multiple records qualify equally, there will be an internal sort order.

3.14.4.40.2.1. SN Score

3.14.4.40.2.2. GN Score

3.14.4.40.2.3. DOB Level

3.14.4.40.2.4. Refusal Code Level

3.14.4.40.2.5. COB Relationship

- 3.14.4.1. The HFS will return the top n records to the central CLASS-E sorter.
  - 3.14.4.41.1. The number of records to be returned will be a system setting.

#### 3.15. LINGUISTIC TRACE FACILITY MODULE DECOMPOSITION

#### 3.15.1. Identification

This module is known as the Linguistic Trace Facility (LTF).

# 3.15.2. **Type**

The LTF is a program that will interact with any or all modules and functions within those modules.

#### 3.15.3. Purpose

The LTF will allow system evaluators to access information about the system functions so that the quality of the content can be ensured. To diagnose and remedy problems associated with questionable system results, evaluators must have access to the results of system functionality at various points during the processing cycle.

### 3.15.4. Function

- 3.15.4.1. The LTF will be a mechanism that will copy and divert statistics, information, processing results to a file outside the main processing module.
- 3.15.4.2. The file will be readily accessible for on-line examination by system evaluators.
- 3.15.4.3. Multiple trace points will be identified when the system is built.
- 3.15.4.4. Examples of trace points:
  - Derived record formats
  - All keys generated for a query and for an add

HNA-E Language Analysis Systems, Inc.

- · Records qualifying with the LFDI\_KEY
- SN and GN DI\_VAL
- SN\_VAL and GN\_VAL
- · Record Gender
- RL#, YOB#, COB# Values
- Sort considerations.

# 4. DATA DECOMPOSITION

#### 4.1. DATA

- 4.1.1. The input data for an HNA-E query will contain all information that is currently required by CLASS.
- 4.1.2. The input data for an HNA-E query will be in the standard format currently required by CLASS.
  - NAME (Surname, Given Name);
    - The SN is a required name field and therefore must be filled.
    - Last Name Unknown (LNU) is not a permitted string in HNA-E.
    - The SN may be represented by a single character, which will be interpreted as an initial.
  - DOB (Date of Birth; Day Month Year); and
  - · COB (Country of Birth; FIPS codes).
- 4.1.3. In addition, the following will be specified:
  - Applicant Gender (AG): Male (M), Female (F), Unknown/Ambiguous (U).
  - A unique identifier (UID) (as defined in CLASS-E).
- 4.1.4. For record adds, additional record information will be entered, as required by CLASS and CLASS-E: e.g., refusal code, province of birth.

#### 4.2. DATA COLLECTION

- 4.2.1. Two alternative approaches to tagging the name data are available: the name as an object and the name as a data element.
- 4.2.2. The system could define the name as an object that knows something about itself and collects information as it passes through the various processing modules.
  - 4.2.2.1. A name object would make the relevant information available to the various processing modules, as needed, from one consistent, predefined object.
- 4.2.2.2. A name object may also permit the same name to be handled in the same way on another occasion. Reuse of information would be especially valuable for HF names.
- 4.2.3. The second, alternative approach is to tag the specific items as they undergo processing or change, to access information in data stores as it is needed, and to tag the name or name segment for the relevant processes it undergoes.

#### 4.3. DATA STORES

- 4.3.1. Several of the Data Stores proposed could be collapsed into one data store (e.g., the HF SN Data Stores: HFST and HFSV); for ease and clarity of exposition and reference, the data stores have been maintained separately.
- 4.3.2. HNA-E will access X Data Stores:
  - Hispanic TAQ Data Store (HTD)
  - High Frequency Surname Type Data Store (HFST)
  - High Frequency Surname Variant Data Store (HFSV)
  - Low Frequency Surname Type Data Store (LFST)
  - Hispanic Given Name Type Data Store (HGT)
  - High Frequency Given Name Variant Data Store (HFGV)
  - Hispanic Character Data Store (HCD)
  - Hispanic Parameter Data Store (HPD)
  - High Frequency Decision Matrix (HDM)
  - Refusal Code Level Data Store (RCL
  - Year-of-Birth Range Data Store (YR)
  - Refusal Code Level/Year-of-Birth Range Data Store (RLYOB)
  - Country-of-Birth Proximity Data Store (COBPROX)
  - Hispanic Country-of-Birth Category Data Store (HCOB)
- 4.4. HISPANIC TITLE/AFFIX/QUALIFIER DATA STORE DECOMPOSITION Because the HNA-E design is viewed as an independent sub-program of the CLASS-E system, the Hispanic Title/Affix/Qualifier Data Store is presented here as

a separate table. It is strongly suggested, however, that CLASS-E support <u>one</u> TAQ Data Store in which the cultural affinity of each TAQ segment is indicated. This will reduce table maintenance and will provide a global picture of the handling of TAOs.

# 4.4.1. Identification

This data store is known as the Hispanic Title/Affix/Qualifier (TAQ) Data Store (HTD).

#### 4.4.2. Type

- 4.4.2.1. The HTD is a data store that contains the Hispanic-specific Title, Affix and Qualifier segments with additional information about the disposition of the items.
- 4.4.2.2. The HTD will be accessed by the Hispanic Name Preprocessor (HNP) and the Hispanic Filter and Sorter (HFS).
- 4.4.2.3. The format of the HTD will be

Figure 53: Format: Hispanic TAQ Data Store (HTD)

DATA FIELD	DATA TYPE	FIELD SIZE	DATA RANGE/VALUE
ID_NO	integer	4	09999
TAQ_FORM	character	15	alphabetics
TAQ_TYPE	character	1	T, I, P, S Q
DELETE	integer	1	1, 0 (True, False)
DISREGARD	integer	1	1, 0 (True, False)
REMOVE	integer	1	1, 0 (True, False)

#### 4.4.2.4. Definitions

- 4.4.2.4.1. ID\_NO: a unique, arbitrary number that identifies the TAQ segment.
- 4.4.2.4.2. TAQ\_FORM: the string that represents the TAQ; the TAQ\_FORM may be a multipart string (i.e., a string that includes internal white space).
- 4.4.2.4.3. TAQ\_TYPE: an indicator of the kind of TAQ segment present: a title (T), prefix (P), infix (I), suffix (S), or qualifier (Q).

#### 4.4.2.4.4. DELETE:

- 4.4.2.4.4.1. The segment is to be removed from all further consideration in the name search process.
  - 4.4.2.4.4.2. The segment is referenced in the filtering process.
  - 4.4.2.4.4.3. The segment is not removed from the original record and is returned with the record to the user.

4.4.2.4.4.4. True (1) or False (0) indicates whether or not this function is to apply to the segment(s) under consideration.

#### 4.4.2.4.5. DISREGARD:

- 4.4.2.4.5.1. The segment is to be removed from further consideration in the name search process but will undergo special evaluation in the filtering process. It will be returned with the record to the user.
- 4.4.2.4.5.2. True (1) or False (0) indicates whether or not this function is to apply to the segment(s) under consideration.

#### 4.4.2.4.6. REMOVE:

- 4.4.2.4.6.1. The segment occurs attached to the name stem.
- 4.4.2.4.6.2. The conjoined TAQ will be separated from a base name segment. (See Section 3.5.4.4.3).
- 4.4.2.4.6.3. True (1) or False (0) indicates whether or not this function is to apply to the segment(s) under consideration.
- 4.4.2.4.6.4. The separated segment will also be marked for DELETE/DISREGARD treatment.

#### 4.4.3. Purpose

Peripheral elements (Titles, Affixes, and Qualifiers) in names do not contribute as much to the name evaluation as does the name stem. Identifying and removing these elements in the name processing component is important. They do, however, contribute to the overall value of a name when determining the proximity of one name to another. They will therefore contribute some value to the filtering and sorting processes.

# 4.4.4. Function

The HTD serves as a repository for all TAQ values and for the treatment that each will be subjected to.

# 4.5. HIGH FREQUENCY SURNAME TYPE DATA STORE DECOMPOSITION

#### 4.5.1. Identification

- 4.5.1.1. This data store is known as the High Frequency Surname Type Data Store (HFST).
- 4.5.1.2. This data store could be merged with the High Frequency Surname Variant Data Store (HFSV).
  - 4.5.1.2.1. The ID\_NO would be different in the HFSV and would serve as a unique identifier for each entry.

- 4.5.1.2.2. The set of HFSN\_TYPEs, with no variants, would be derivable from the HFSN\_VARs with a DI\_VAL equal to 1.00.
- 4.5.1.2.3. The SET\_ID of the HFST and HFSV would be the same.

### 4.5.2. Type

- 4.5.2.1. The HFST data store consists of the 500 most frequently occurring HF SN segment types (i.e., unique occurrence).
- 4.5.2.2. The HFST will be accessed by the Hispanic Surname Segmenter, Hispanic Segment Positioner, and the Frequency Path Director modules.
- 4.5.2.3. The format of the HFST will be

Figure 54: Format: High Frequency Surname Type Data Store (HFST)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE
ID NO	integer	4	19999
HFSN TYPE	character	24	alphabetics
SET ID	integer	4	19999

Figure 55: Example: Piece of HFST

ID_NO	HFSN_TYPE	SET_ID
0001	GARCIA	0001
0002	RODRIGUEZ	0002
0003	HERNANDEZ	0003
0004	LOPEZ	0004
0005	MARTINEZ	0005
0006	GONZALEZ	0006
0007	PEREZ	0007
0008	SANCHEZ	0008
0009	RAMIREZ	0009
0010	GOMEZ	0010
0011		0011

#### 4.5.2.4. Definitions

- 4.5.2.4.1. ID\_NO will be a unique numerical identifier for each of the HF SN segments, HFSN\_TYPEs.
- 4.5.2.4.2. HFSN\_TYPE will contain a unique character string that represents one of the 500 most frequently occurring Hispanic surname stems.
- 4.5.2.4.3. SET\_ID will be the unique identifier for the *set* of variants of the HFSN\_TYPE and will be used as the HFSN\_KEY.

# 4.6. HIGH FREQUENCY SURNAME VARIANT DATA STORE DECOMPOSITION

# 4.6.1. Identification

- 4.6.1.1. This data store is known as the High Frequency Surname Variant Data Store (HFSV).
- 4.6.1.2. This data store will be updated in real time as variants qualify for inclusion in the data store. (See Section 3.12.4.38)
- 4.6.1.3. This data store could be merged with the HFST (See Section 4.5.1.2.)

#### 4.6.2. Type

- 4.6.2.1. The HFSV is a data store that consists of a HFSN\_TYPE segment with a variant of that segment and a value that represents the degree of digraph proximity of the HFSN\_TYPE and its variant.
- 4.6.2.2. The HFSV is a data store that will have between 75,000 and 100,000 rows.
- 4.6.2.3. A name segment may be the variant of more than one HFSN\_TYPE.
- 4.6.2.4. The HFSV will be accessed by the High Frequency Processor and Low Frequency Processor.
- 4.6.2.5. The format of the HFSV will be

Figure 56: Format: High Frequency Surname Variant Data Store (HFSV)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE
ID NO	integer	6	000000999999
HFSN_VAR	character	24	alphabetics
SET ID	integer	4	00009999
DI_VAL	decimal	4	0.001.00

Figure 57: Example: High Frequency Surname Variant Data Store

ID_NO	HFSN_VAR	SET_ID	DI_VAL
032711	PEREZ	0007	1.00
032712	PERES	0007	0.67
032713	PEREZA	0007	0.77
016976	GOMEZ	0010	1.00
016977	GOMES	0010	0.67
016978	BOMEZ	0010	0.67

## 4.6.2.6. Definitions

4.6.2.6.1. ID\_NO will be a unique numerical identifier for each HFSN\_VAR entry.

HNA-E Language Analysis Systems, Inc.

- 4.6.2.6.2. HFSN\_VAR will contain a character string that has been determined to be a variant of the HFSN\_TYPE with which it is associated. A HFSN\_VAR may be a variant of one or more of the HFSN\_TYPEs.
  - 4.6.2.6.2.1. A variant is defined as a name stem that shares a sufficient number of digraphs (strings of two characters) with the HFSN\_TYPE to pass a pre-determined threshold.
  - 4.6.2.6.2.2. A HFSN\_TYPE can be obtained from the HFST or from the HFSV as a HFSN\_VAR with a DI\_VAL equal to 1.00.
- 4.6.2.6.3. DI\_VAL is a two-place decimal value that represents the proximity of the HFSN\_TYPE and the HFSN\_VAR.
  - 4.6.2.6.3.1. The DI\_VAL is a calculation derived from the shared digraphs (strings of two characters) of the HFSN\_TYPE and the HFSN\_VAR associated with it.
  - 4.6.2.6.3.2. The calculation is determined in the following way:
    - 4.6.2.6.3.2.1. The digraphs are identified for each name stem, the HFSN\_TYPE (Comparand #1) and the HFSN\_VAR (Comparand #2).
      - 4.6.2.6.3.2.1.1. Each pair of alphabetic characters is identified: GOMEZ

        → GO / OM / ME / EZ
      - 4.6.2.6.3.2.1.2. A digraph is also formed of the initial boundary (#) and the first alphabetic character:

        GOMEZ → #G.
      - 4.6.2.6.3.2.1.3. A digraph is also formed of the final alphabetic character and the final boundary (#): GOMEZ

        → Z#.
    - 4.6.2.6.3.2.2. The number of shared digraphs is calculated; a digraph may match one digraph only.
    - 4.6.2.6.3.2.3. The number of shared digraphs is multiplied by 2 and divided by the total number of digraphs in comparand #1 added to the total number of digraphs in comparand #2.
    - 4.6.2.6.3.2.4. The formula is:

2 \* d / a + b, where d = the total number of shared digraphs; where a = the total number of digraphs in Comparand #1 and where b = the total number of digraphs in Comparand #2.

Figure 58: Example: Digraph Evaluation of Two Comparands

COMPARANDS	DIGRAPHS	SHARED DIGRAPHS (d)	DI_VAL
	#D DO OM MI IN NG GU UE EZ Z#	#D DO OM MI IN UE	2*d/a+b=12/20
DOMINGUEZ			
	#D DO OM MI IN NQ QU UE ES S#	= 6	.60
DOMINOUES			

# 4.6.3. Purpose

- 4.6.3.1. For HNA-E to be an effective retrieval system, it must be able to retrieve variants of query names. The impact on system performance can be dramatic, however, if traditional matching techniques are used to identify variant names. By assigning variants to the same set and recording their digraph value, querying a HF surname will result in the direct retrieval of variant records and their digraph values.
- 4.6.3.2. The HFSV also serves as a resource for identifying which HF surnames are related to a LF surname.

# 4.6.4. Function

The HFSV Data Store will be dynamically updated. (See Section 3.12.4.38 for details.)

# 4.7. HIGH FREQUENCY DECISION MATRIX DATA STORE

#### 4.7.1. Identification

This data store is known as the High Frequency Decision Matrix (HDM).

# 4.7.2. Type

- 4.7.2.1. The HDM is a data store that will provide criteria for database record retrieval for query records with HF name segments.
- 4.7.2.2. It will be accessed by the High Frequency Processor (HFP).

Figure 59: Format: Hispanic Decision Matrix (HDM)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE
OUERY SN FORMAT	character	2	A, B
DATABASE SN FORMAT	character	2	A, B, C
YOB RANGE (YOB#)	integer	1	06
REFUSAL CODE LEVEL	integer	1	04
(RL#)			
RECORD GENDER (RGNDR)	character	1 ,3	М, F, <u>U</u>

Figure 60: Example: Hispanic Decision Matrix (HDM) (Values for example only)

	Single-Segment SN							Two-Seg	ment SN	l .		
OUERY SN FORMAT	Α	Α.	Α		AB	AB	AB	AB	AB	AB	AB	AB
DATABASE SN FORMATS	Α	AB	BA		AB	BA	Α	В	AC	CA	CB	BC
YOB#	5	5	2		5	4	4	2	2 _	0	0	0
RL#	4	4	3		4	4	4	1	1	0	0	0_
RCNDR	MFU	MFU	MFU	1	MFU	MFU	MFU	MFU	FU	MFU	MFU	MFU

#### 4.7.3. Definitions

- 4.7.3.1. QUERY SN FORMAT: is a character string that is an abstract representation of the query SN. Each segment is represented by a single character, the leftmost A, the next B. The sequence also represents the position of the segment.
- 4.7.3.2. DATABASE SN FORMAT: is a character string that is an abstract representation of the possible and acceptable variations in the query SN which are relevant to the QUERY SN FORMAT and which will be retrieved from the database, given the conditions stipulated in the YOB RANGE (YOB#), REFUSAL CODE LEVEL (RL#) and RECORD GENDER (RGNDR). Each segment is represented by a single character.
  - 4.7.3.2.1. If the character is the same as a character in the QUERY SN FORMAT, it represents the same SN Key.
  - 4.7.3.2.2. If the character is different from a character in the QUERY SN FORMAT, it represents a different SN Key.
  - 4.7.3.2.3. If the character is in the same relative position as that in the query SN, it represents the same position in the SN string.
  - 4.7.3.2.4. If the character in not in the same relative position as that in the query SN, it represents a different (out-of) position in the SN string.

- 4.7.3.3. YOB RANGE (YOB#): is an integer that represents a YOB range specified in the YOB RANGE (YR) Data Store. (N.B. In this scheme, YOB# integer does not represent the year range itself. It refers to a table that specifies that YOB2, for example, represents an exact year-of-birth and that YOB3 represents a range of 1 year on either side of the query year (for a range total of 3 years).)
- 4.7.3.4. REFUSAL CODE LEVEL (RL#): is an integer that represents a Refusal Code Level specified in the REFUSAL CODE LEVEL Data Store. (N.B. In this scheme, this number represents a set of Refusal Codes that has a pre-determined degree of seriousness. The number given here does not signal the Refusal Code itself. The number is expanded in the Refusal Code Level Data Store, where 0, for example, might represent a 00 Refusal Code.)
- 4.7.3.5. RECORD GENDER (RGNDR): is a set of up to three characters that represent the required Record Gender of the database record.

#### 4.7.4. Purpose

Many Hispanic surnames occur with very high frequency; they also generally have at least two segments. Any retrieval system that captures only one of these names will have an inordinately high recall. Many of these records will not be at all relevant to the query record. Special treatment of high frequency names must entail some method of reducing the number of irrelevant records retrieved from the database. The HDM provides the information about how to delimit the records that will be retrieved from the database. A reduction in the recall will reduce post-processing time.

#### 4.7.5. Function

The HDM is a data store that consists of qualifying and delimiting criteria.

- 4.7.5.1. Qualifying criteria will be the number of SN segments, SN content, and SN segment positions.
- 4.7.5.2. Delimiting criteria will be Year-of-Birth (YOB) Range (YR), Refusal Code (RC) Level (RL) and Record Gender (RGNDR).
  - 4.7.5.2.1. The qualifying criteria will produce a set of SN formats to retrieve from the database.
  - 4.7.5.2.2. The delimiting criteria will specify the YOB range, maximum RC Level for each of the SN formats and Record Gender limitations, if any.

# 4.8. HISPANIC GIVEN NAME TYPE DATA STORE DECOMPOSITION

#### ·4.8.1. Identification

- 4.8.1.1. This data store is known as the Hispanic Given Name Type Data Store (HGT).
- 4.8.1.2. This data store could be merged with the High Frequency Given Name Variant Data Store (HFGV).
  - 4.8.1.2.1. The ID\_NO would be different in the HFGV and would serve as a unique identifier for each entry.
  - 4.8.1.2.2. The set of HFGN\_TYPEs, with no variants, would be derivable from the HFGN\_VARs with a DI\_VAL equal to 1.00.
  - 4.8.1.2.3. The SET\_ID of the HFGT and HFGV would be the same.

# 4.8.2. Type

- 4.8.2.1. The HGT data store will consist of up to ten thousand entries.
- 4.8.2.2. The HGT will be accessed by the Hispanic Gender Identifier, Frequency Path Director (FPD), the High Frequency Processor.
- 4.8.2.3. The HGT will have the following format:

Figure 61: Format: Hispanic Given Name Type Data Store (HGT)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE
ID_NO	integer	4	00009999
GN TYPE	character	. 24	alphabetics
SET_ID	integer	3	001999
HI_FREQ	integer	1	1, 0 (True, False)
GNDR	character	1	M, F, U

Figure 62: Example: Hispanic Given Name Type Data Store (HGT)

ID_NO	GN_TYPE	SET_ID_	HI_FREQ	GNDR
0001	JOSE	0001	1	M
0002	MARIA	0002	1	F
0003	JUAN	0003	l	M
0004	LUIS	0004	1	М
0005	ANTONIO	0005	l l	M
0006	CARLOS	0006	1	M
0007	JESUS	0007	l	M
0008	MANUEL	0008	1	M
0009	FRANCISCO	0009	1	M
0010	JORGE	0010	1	M
0011		0011		
2367	DAGOBERTO	0000	0	M

# 4.8.2.4. Definitions

- 4.8.2.4.1. ID\_NO: is an integer that is a unique numerical identifier for each of the GN\_TYPEs.
- 4.8.2.4.2. GN\_TYPE: is a a character string that represents one of up to ten thousand Hispanic given name stems.
  - 4.8.2.4.2.1. A HFGN\_TYPE is a GN\_TYPE whose HI\_FREQ value is 1 (True).
- 4.8.2.4.3. SET\_ID: is an integer that is the numerical identifier for the set of related variants of the GN\_TYPE that is HF.
  - 4.8.2.4.3.1. The SET\_ID will serve as the HFGN\_KEY.
  - 4.8.2.4.3.2. Not every entry in the HGT will have a unique SET\_ID; a distinct SET\_ID is reserved for those GN\_TYPEs where HI\_FREQ is True (1).
- 4.8.2.4.4. HI\_FREQ: is an integer (1, 0/True, False) that indicates if the GN\_TYPE is or is not a HF GN segment.
  - 4.8.2.4.4.1. The frequency of all GN\_TYPEs will be specified.
  - 4.8.2.4.4.2. True (1) will indicate a HF segment.
  - 4.8.2.4.4.3. False (0) will indicate a LF segment.
- 4.8.2.4.5. GNDR: is a single character value that indicates the gender of the GN\_TYPE.
  - 4.8.2.4.5.1. If the name is predictably female, the value will be
  - 4.8.2.4.5.2. If the name is predictably male, the value will be M.
  - 4.8.2.4.5.3. If the name is ambiguous or unknown, the value will be U.

# 4.8.3. Purpose

The HGT provides information about Hispanic given name segments. It indicates the frequency of the segments, their gender and the set of names of which they are the parent.

#### 4.8.4. Function

The HGT serves as a resource for Hispanic Gender Identifier and the High Frequency Processor.

# 4.9. HIGH FREQUENCY GIVEN NAME VARIANT DATA STORE DECOMPOSITION

#### 4.9.1. Identification

This data store is known as the High Frequency Given Name Variant Data Store (HFGV).

# 4.9.2. **Type**

- 4.9.2.1. The HFGV will be accessed by the High Frequency Processor.
- 4.9.2.2. The HFGV will have about 60,000 to 90,000 rows.
- 4.9.2.3. The HFGV will have the following format:

Figure 63: Format: High Frequency Given Name Variant Data Store (HFGV)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE
ID_NO	integer	5	0000099999
HFGN_VAR	character	24	alphabetics
SET_ID	integer	4	00009999
DI_VAL	decimal	4	0.001.00

Figure 64: Example: Piece of HFGV

ID_NO	HFGN_VAR	SET_ID	DI_VAL
00001	JOSE	1000	1.00
00002	JOSEA	0001	0.73
00003	JOSSE	0001	0.73
00004	MARIA	0002	1.00
00005	MIRIA	0002	0.67
00006	MIRIAM	0164	1.00
00007	MIRIA	0164	0.77

# 4.9.2.4. Definitions

- 4.9.2.4.1. ID\_NO: is a unique numerical identifier for each HFGN\_VAR entry in the HFGV data store.
- 4.9.2.4.2. HFGN\_VAR: is character string that represents a GN segment that is a digraph variant of the HFGN\_TYPE (HFGN\_VAR whose DI\_VAL = 1.00).
- 4.9.2.4.3. SET\_ID: is a unique identifier of the set of GN segments. that are variants of the same HFGN\_TYPE.
- 4.9.2.4.4. DI\_VAL: is a two-place decimal value that indicates the digraph relationship between the HFGN\_VAR and its parents HFGN\_TYPE.

# 4.9.3. Purpose

The HFGV is a resource for defining the given name segments that will be stored with records added to the database. Storage of information about variant relations will speed retrieval and the filtering process.

# 4.9.4. Function

The HFGV will be accessed by the HFP to assign keys to given name segments on record add and query.

4.10. LOW FREQUENCY SURNAME TYPE DATA STORE DECOMPOSITION

#### 4.10.1. Identification

This data store is known as the Low Frequency Surname Type Data Store (LFST).

# 4.10.2. Type

- 4.10.2.1. The LFST is a data store of LF keys.
- 4.10.2.2. The LFST will have about 900,000 to 1 million rows.
- 4.10.2.3. The LFST will have the following format:

Figure 65: Format: Low Frequency Surname Type Data Store (LFST)

DATA TYPE	FIELD SIZE	VALUE RANGE
integer	6	000001999999
character	24	alphabetics
character	3	alphanumerics; char + char + #
	integer character	integer 6 character 24

Figure 66: Example: Piece of LFST

ID_NO	LFSN_TYPE	LFDIKEY
000001	AALVAREZ	AAl
000001	AALVAREZ	AA2
000001	AALVAREZ	AL2
000001	AALVAREZ	ALI
000001	AALVAREZ	AL3
000001	AALVAREZ	LV3
000001	AALVAREZ	LV2
000001	AALVAREZ	LV4
000001	AALVAREZ	VA4
000001	AALVAREZ	VA3
000098	BARRIOS	BAI
000098	BARRIOS	BA2

# 4.10.2.4. Definitions:

- 4.10.2.4.1. ID\_NO: is an arbitrary numerical reference to each LFSN\_TYPE. The ID\_NO will serve as the DI\_KEY.
- 4.10.2.4.2. LFSN\_TYPE: is the unique low frequency name segment as it occurs in the database; if there are multiple occurrences of the same name, they are represented by one entry, hence the term "type."

- 4.10.2.4.3. LFDIKEY: is a string of alphanumeric characters that represents one digraph and its actual or derived position.
  - 4.10.2.4.3.1. Up to ten LFDIKEYs will be associated with each LFSN\_TYPE.
  - 4.10.2.4.3.2. An LFDIKEY is name-specific, so the same key may appear with other LFSN\_TYPEs, in which case it will have a different ID\_NO.

# 4.10.2.4.3.3. A LFDIKEY is

- a digraph formed from the LF SN segment beginning with the leftmost character and its position (Base Key) and
- 2) a positional variant on that digraph key (Position Key).
- 4.10.2.4.3.4. Positional information will be associated with each digraph.
- 4.10.2.4.3.5. To form a key, begin with the leftmost character and generate four digraph keys (Base Key) from the five leftmost characters of the LF SN segment. The first two characters form a digraph, the second and third characters form a digraph, the third and fourth characters form a digraph and the fourth and fifth characters form a digraph. Positional information (Positions 1, 2, 3, 4) will be included.
- 4.10.2.4.3.6. Generate, from the Base Keys, up to six additional Position Keys; the position keys have the same characters as the Base Keys but contain different positional information. A maximum of ten keys (Base + Position) will be generated.
  - 4.10.2.4.3.6.1. Produce a Position Key on the first Base Key with Position 2.
  - 4.10.2.4.3.6.2. Produce Position Keys on the second Base Key with Position 1 and Position 3.
  - 4.10.2.4.3.6.3. Produce Position Keys on the third Base Key with Position 2 and Position 4.
  - 4.10.2.4.3.6.4. Produce a Position Key on the fourth Base Key with Position 3. No Position Key is generated for Position 5 because the maximum of 10 keys has been reached.

### 4.10.3. Purpose

The LFST provides information that will limit the search of database records. - Preprocessing of name types allows identification of relevant name segments without having to examine database records directly.

#### 4.10.4. Function

The LFST will be accessed by the LFP.

# 4.11. HISPANIC CHARACTER DATA STORE

# 4.11.1. Identification

This data store is known as the Hispanic Character Data Store (HCD).

#### 4.11.2. Type

- 4.11.2.1. The HCD is a data store of all characters in Hispanic names and their predictable variants.
- 4.11.2.2. The format of the HCD will be:

Figure 67: Format: Hispanic Character Data Store (HCD)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE
SET_ID	integer	3	000999
CHAR	· character	1	alphabetics
CHAR VAR	character	1	alphabetics

Figure 68: Example: Piece of HCD

SET_ID	CHAR	CHAR_VAR
001	В	В
001	В	V
002	S	S
002	S	Z
004	С	С
004	С	S
037	F	F
052	K	K
078	M	M
078	М	N

#### 4.11.2.3. Definitions

- 4.11.2.3.1. SET\_ID: is an arbitrary numerical that represents the set of characters that vary with one another. The SET\_ID will be the GN\_INIT Key.
- 4.11.2.3.2. CHAR: is a single alphabetic character. Every alphabetic character will be représented. The CHAR is the type of

character, which may or may not have variants (CHAR\_VAR).

4.11.2.3.3. CHAR\_VAR: is a single alphabetic character that may or may not vary predictably with other characters in written Spanish. A single character may participate in more than one set

#### 4.11.3. Purpose

diani.

Retrieval of records with HF SN segments from the database will be limited by the initial of the GN segments. For the retrieval to be sufficiently robust, however, the system must allow for some variation in the GN initials. The HCD indicates variations on initials.

# 4.11.4. Function

The HCD will be accessed by the HFP and will provide the source of the GN\_INIT Keys that are to be generated for HF searches.

# 4.12. TAQ FILTER DATA STORE DECOMPOSITION

#### 4.12.1. Identification

This data store is known as the TAQ Filter Data Store (TF).

# 4.12.2. Type

- 4.12.2.1. This TF will be accessed by the Hispanic Filter and Sorter and provides parameter factors for matching TAQ DISREGARD tags during record filtering.
- 4.12.2.2. The format of the TF follows:

Figure 69: Format: TAQ Filter Matrix Design

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE	DATA VALUE
TAODIS#1	character	8	alphabetics	TAQ_DISREGARD ITEM
TAODIS#2	character	. 8	alphabetics	TAQ_DISREGARD ITEM
TF_VALUE	decimal	4	0.001.00	Various (TBD)

Figure 70: Example: Piece of TF (Values are for example only)

2.3.0

#### 4.12.2.3. Definitions

- 4.12.2.3.1. TAQDIS#1: is the TAQ DISREGARD segment that occurs in one or the other (different) of the comparands.
- 4.12.2.3.2. TAQDIS#2: is the TAQ DISREGARD segment that occurs in one or the other (different) of the comparands.
- 4.12.2.3.3. TF\_VALUE: is the factor that will be used to adjust the SN\_VAL or GN\_VAL if the TAQDIS#1 and TAQDIS#2 are present in the comparands.

#### 4.12.3. Purpose

Hispanic names often have peripheral name elements. Some of these make up a segment of the name, the TAQ values identified in the TF. Their relative value, however, varies. Some of them cannot cooccur, some have opposite meanings, so it is necessary to identify their relative value when they are contrasted with one another.

#### 4.12.4. Function

The TF provides the resources for the HFS to determine the relative value of TAQs that occur in two comparands.

4.13. HISPANIC PARAMETER DATA STORE DECOMPOSITION

#### 4.13.1. Identification

This module is known as the Hispanic Parameter Data Store (HPD).

8

03/19/98

# 4.13.2. **Type**

2.00

- 4.13.2.1. The HPD is a data store that will be accessed by the Filter Component of the Hispanic Filter and Sorter (HFS).
- 4.13.2.2. The HPD is a parameter table that will be accessible to the user and whose cell values will be determined through testing and comparative evaluation.
- 4.13.2.3. The HPD has the following format:

Figure 71. Format: Hispanic Parameter Data Store (HPD)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE	DATA VALUE
PARM_NAME	character	6	alphabetics	SNTHR, GNTHR, OPSVAL, OPGVAL, INITSN, INITGN, RGNDR, TAQASN, TAQAGN, TAQXSN, TAQXGN, RL#, YOB#, COB#, etc.
PARM_VAL	decimal	4	0.001.99	Various (TBD)

Figure 72: Example: HPD (Values are for example only.)

COB3	1.10
COB4	1.00
COB5	0.95

4.13.2.4. The values provided are for example only and do not necessarily represent the PARM\_VALs to be used for the parameters.

#### 4.13.3. Purpose

The HPD is a data store that allows easy access to adjustable thresholds for record qualification, to thresholds for data store updates, and to parameters that contribute to the determination of the name scores (SN\_VAL, GN\_VAL) and to the Composite Score of two record comparands.

# 4.13.4. Function

The HP functions as an independent data store with thresholds needed by the LFP and all the parameters needed by the HFS during the filtering process.

# 4.14. REFUSAL CODE CATEGORY DATA STORE DECOMPOSITION

#### 4.14.1. Identification

This data store is known as the Refusal Code Level Data Store (RCL).

#### 4.14.2. Type

- 4.14.2.1. It is recommended that the RCL be a parameter file, which can be accessed by the client so RC categories can be added to or changed with
- 4.14.2.2. The RC data store will provide a list of the Refusal Codes and its Refusal Category, which is an indication of the level of seriousness of each Refusal Code.
- 4.14.2.3. The RCL will be referred to by the Hispanic Decision Matrix (HDM) and by the LFP and Hispanic Filter and Sorter.
- 4.14.2.4. The RCL has the following format:

Figure 73: Format: Refusal Code Level Data Store (RCL)

DATA FIELD	DATA TYPE	FIELD SIZE	DATA VALUE
REFUSAL CODE	alphanumerics	3	Standard Refusal Codes
REF_CAT	alphanumerics	3	RL0, RL1, RL2, RL3, RL4

Figure 74: Example: RCL (REF\_CATs for example only)

REFUSAL CODE	REF_CAT
00	RL0
23	RLi
6C	RL2
07	RL3
G	RL4

# 4.14.2.5. Definitions

- 4.14.2.5.1. REFUSAL CODE: indicates each Visa Refusal Code (Codes and their Refusal Level (see VALUE) are for example only; they do not represent the complete list nor the accurate assignment of a Refusal Code to a Refusal Level).
- 4.14.2.5.2. REF\_CAT: The RL# will appear in the form RL1, RL2,
  - 4.14.2.5.2.1. RL# is the Refusal Category to which a particular Refusal Code has been assigned. The Visa Office will assign Refusal Codes to one of 4 categories: RL1, RL2, RL3, RL4; RL0 is reserved for the Refusal Code 00. (The current distinction among Refusal Codes is a binary one: serious and non-serious. Assignment of Refusal Codes to more groups has not yet been done; the consequence is that one or more of these categories may not currently have a distinct value.) The RL# occurs in ascending order, from most serious to least serious Refusal Code. The RL# will be linked to a Year-of-

Birth Code (see Section 4.16) to determine the relevant subsets of records to be searched.

- 4.14.2.5.2.2. RC0 refers to the Refusal Code 00
- 4.14.2.5.2.3. RC1 refers to all Refusal Codes that have been designated as Type 1 Serious RC 1, i.e., the most serious, excluding 00.
- 4.14.2.5.2.4. RC2 refers to all Refusal Codes that have been designated as Type 2 Serious RC, i.e., serious but less serious than RC0 and RC1.
- 4.14.2.5.2.5. RC3 refers to all Refusal Codes that have been designated as Type 1 Non-Serious RC. These codes are less serious than the RC0, RC1 and RC2 codes.
- 4.14.2.5.2.6. RC4 refers to Refusal Codes that have been designated as Type 2 Non-Serious. These codes are the least serious codes, less serious than the RC0, RC1, RC2 and RC3 codes.

### 4.14.3. Purpose

It has long been desirable to make more granular distinctions among the Refusal Codes. For many years, DOS has maintained a distinction between serious and non-serious codes; these different categories were correlated with different YOB search ranges. However, a mechanism for making greater distinctions will provide greater flexibility in delimiting the set to be retrieved during the first stage of record analysis, especially for Hispanic high frequency names, where more restricted retrievals are highly desirable. The introduction of five refusal code levels also provides the opportunity to correlate more year-of-birth ranges to the refusal code levels.

#### 4.14.4. Function

The RCL provides information needed for the evaluation of record proximity in the Hispanic filtering process and contributes to the delimitation of database records retrieved through the RLYOB Data Store.

# 4.15. YEAR-OF-BIRTH RANGE DATA STORE DECOMPOSITION

# 4.15.1. Identification

This data store is known as the Year-of-Birth Range Data Store (YR).

# 4.15.2. Type

- 4.15.2.1. It is recommended that the YR be a parameter file, which can be accessed by the client so YOB ranges can be set. Alternatively, it could be represented as a system parameter whose value(s) are set in an .ini file
- 4.15.2.2. The YR will define the YOB ranges that will be associated with a Refusal Level (see Section 4.16).
- 4.15.2.3. This data store has the following format:

Figure 75: Format: Year-of-Birth Range Data Store (YR)

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE	DATA DEFINITION
YOB0	integer	1	0	exact date of birth
YOB1	character	1	Α	exact year, inverted month and day
YOB2	character	l	В	exact year of birth
YOB3	integer	2	199	narrow year of birth range
YOB4	integer	2	199	standard year of birth range
YOB5	integer	2	199	wide year of birth range
YOB6	integer	2	199	unlimited year of birth range

# 4.15.2.4. Definitions

- 4.15.2.4.1. YOB# is the Year-of-Birth Range category whose value indicates the year-of-birth range to be searched. The year-of-birth VALUE indicates the search range, that is, the number of years on either side of a given year-of-birth to be searched. For example, if the input year is 1962 and YOB3 range is 4, the search will cover a range of nine years, 1958-1966. The range includes the full year, so all of 1958 and all of 1966.
  - 4.15.2.4.1.1. There are seven YOB# categories, YOB0, YOB1, YOB2, YOB3, YOB 4, YOB5, YOB6.
    - YOB0 is a single integer that refers to an exact month, day, year of birth. If YOB0 is specified, the system must be able to match the month, day and year of the Date of Birth of an input record and a database record.
    - YOB1 is a single character (A) that refers to an exact year-of-birth with the month and day inverted.
      - If YOB1 is specified, the system must be able to match the year of Date of Birth and an inverted month and day (DEC 03 → MAR 12) of the input record and the database record.
      - YOB1 will be relevant to the Hispanic Filter and Sorter, but may not function as a search

parameter since the value would be subsumed in YOB2.

- YOB2 is a single character (B) that refers to an exact year-of-birth. If YOB2 is specified, the system must be able to match the year of the Dateof-Birth of an input record and a database record.
- YOB3 is a one- or two-place integer (1...99) that refers to a narrow year-of-birth range. Narrow yearof-birth range is usually defined as 1 year (for a search range of 3 years).
- YOB4 is one- or two-place integer (1...99) that refers to a standard year-of-birth range. Standard year-of-birth range is usually defined as 3 years (for a search range of 7 years).
- YOB5 is a one- or two-place integer (1...99) that refers to a wide year-of-birth range. Wide year-ofbirth range is usually defined as 5 years (for a search range of 11 years).
- YOB6 is a one- or two-place integer (1...99) that refers to an unlimited or extremely wide year-ofbirth range. Unlimited year-of-birth range would be set sufficiently high to include all (or all desired) years-of-birth in the database (e.g., 50).

#### 4.15.3. Purpose

This YR provides a greater granularity in the year-of-birth range and, therefore, greater flexibility in delimiting the set to be retrieved during the first stage of record analysis. The correlation of five refusal code levels to different year-of-birth ranges will help to delimit the number of records to be searched and to define the more valuable set of records. For the Hispanic processor, greater precision in the year-of-birth range is especially important in the High Frequency Processor where more restricted retrievals are highly desirable.

## 4.15.4. Function

- 4.15.4.1. The YR permits greater granularity in the Date-of-Birth types related to the system.
- 4.15.4.2. The YR will be accessed by the Refusal Code Level/YOB Range Data Store, which will limit the retrieval range in the Hispanic Search Engine.
- 4.15.4.3. The YR data store will define the YOB ranges referred to in the Hispanic Decision Matrix (HDM).
- 4.15.4.4. The YR will contribute to the Hispanic Filter and Sorter to contribute information to the composite score.

# 4.16. REFUSAL CODE LEVEL / YOB RANGE DATA STORE MODULE DECOMPOSITION

#### 4.16.1. Identification \_\_\_\_

This data store is known as the Refusal Code Level/YOB Range Data Store (RLYOB).

# 4.16.2. **Type**

- 4.16.2.1. The RLYOB is a matrix that merges the values in the Refusal Code Level (RCL) Data Store and the Year-of-Birth Range (YR) Data Store.
- 4.16.2.2. For each Refusal Level (RL), a Year-of-Birth (YOB) Range is specified.
  - 4.16.2.2.1. Only one YOB Range for each RL is permitted.
  - 4.16.2.2.2. The same YOB Range may apply to more than one RL.
- 4.16.2.3. The RLYOB has the following format:

Figure 76: Format: Refusal Level/Year-of-Birth Range Data Store (RLYOB)

-[	DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE	DATA VALUE
- [	RL#	character	3	RL04	RL0, RL1, RL2, RL3, RL4
	YOB#	character	4	YOB06	YOBO, YOB1, YOB2, YOB3, YOB4, YOB5, YOB

Figure 77: Example: RLYOB Data Store

RL#	YOB#
RL0	YOB5
RLI	YOB4
RL2	YOB3
RL3	YOB3
RL4	YOB2

#### 4.16.2.4. Definitions:

- 4.16.2.5. RL#: is a character string that indicates the Refusal Level of the Refusal Code.
- 4.16.2.6. YOB#: is a character string that indicates the Date-of-Birth Range Category of the comparands.

#### 4.16.3. Purpose

Retrieval of records from the database should be delimited by a relationship between the Refusal Code Level and the Year-of-Birth Range. It will restrict the number of records to be reviewed.

#### 4.16.4. Function

The RLYOB is a resource for the Hispanic Search Engine to delimit the LF records retrieved from the database.

# 4.17. COUNTRY-OF-BIRTH PROXIMITY DATA STORE

# 4.17.1. Identification

This module is known as the Country-of-Birth Proximity Data Store (COBPROX).

# 4.17.2. **Type**

4.17.2.1. The COBPROX is a data store whose cells contain a decimal value that reflects the degree of relationship between the country represented on two country-of-birth.

4.17.2.2. The COBPROX has the following format:

Figure 78: Design: COBPROX Data Store

DATA FIELD	DATA TYPE	FIELD SIZE	VALUE RANGE	DATA VALUE
COB#1	character	4	alphabetics	COB Code
COB#2	character	4	alphabetics	COB Code
COBVAL	decimal	4	0.001.00	Various

GRBR	VTNM	0.05
VTNM	VTNM	1.00

#### 4.17.2.3. Definitions:

- 4.17.2.3.1. COB#1: is the 4-character Country-of-Birth Code of one of the comparands.
- 4.17.2.3.2. COB#2: is the 4-character Country-of-Birth Code of one of the comparands.
- 4.17.2.3.3. COBVAL: is the decimal value assigned through the HCOB and other COB Category Data Stores that are culture-specific (as they are developed). A default value will be assigned for those COBs that do not enter into special relations. The COBVAL indicates the degree of relationship between the two COBs.

#### - ·4.17.3. Purpose

The COBPROX Data Store provides information on the relative value of the COBs in two comparands. This value can serve to limit the COBs that are accessed for retrieval.

#### 4.17.4. Function

The COBPROX is populated by the HCOB and any other partition-specific Country-of-Birth Category Data Stores. The COBPROX provides COB relationship information.

# 4.18. HISPANIC COUNTRY-OF-BIRTH CATEGORY DATA STORE DECOMPOSTION

#### 4.18.1. Identification

This data store is known as the Hispanic Country-of-Birth Category Data Store (HCOB).

#### 4.18.2. Type

This HCOB is a data store that will serve as the source of information for the COBPROX Data Store, populating the COBVAL, and will provide the COB Category (COBCAT) necessary for the Hispanic Filter and Sorter.

Figure 80: Design: Hispanic Country-of-Birth Category Data Store (HCOB)

VENE	PORT	COB5	0.60
PORT	PORT	COB1	1.00

# 4.18.3. Definitions

ىرائىدۇن. ئۇيران

- 4.18.3.1. COB#1: is the 4-character COB Code of one of the comparands.
- 4.18.3.2. COB#2: is the 4-character COB Code of one of the comparands.
- 4.18.3.3. COBCAT: is the category assigned to the relationship of two COBs.
  - 4.18.3.3.1. Categories might be defined as Exact, State, Geographic Region, Dialect Region.
  - 4.18.3.3.2. All relationships are adjustable.
  - 4.18.3.3.3. Example COB Categories are:
    - COB1: Exact represents an exact match of the COBs: AGS/AGS; the COBPROXVAL would be 1.00.
    - COB2: State Relationship represents the set of COBs that are states within one country (currently only the Mexican States qualify). The score would be something less than that applied to an exact match but nonetheless high: 0.95.
    - COB3: Northern South America represents the set of COBs that are in close geographic proximity and share naming conventions: COL/VENE. The value assigned would be less than that for COB2: 0.85.
    - COB4: All Latin America refers to all COBs in Central and South America and the Spanish-speaking Caribbean. The value assigned would be less than that for COB2: 0.65.
    - COB5: Similar refers to COBs that have qualified as Hispanic but may not exhibit Hispanic naming conventions: Brazil, Portugal.
    - COB6: All refers to all COBs and is assigned a value that will allow the search of all COBs; it would be the lowest decimal value used.

4.18.3.4. COBVAL: is the decimal value that will be assigned to a particular COB relationship; this value will be used to determine the COBs that will be permitted in the retrieval process.

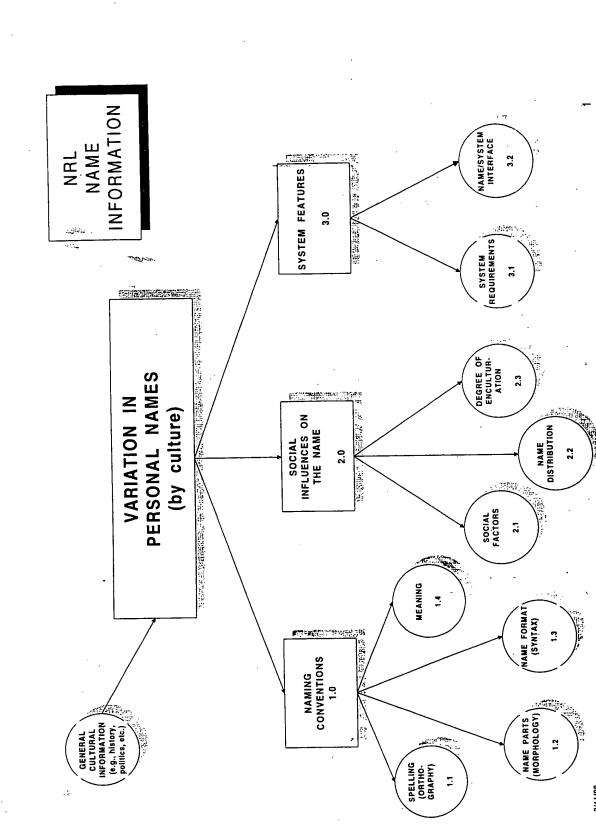

# 4.18.4. Purpose

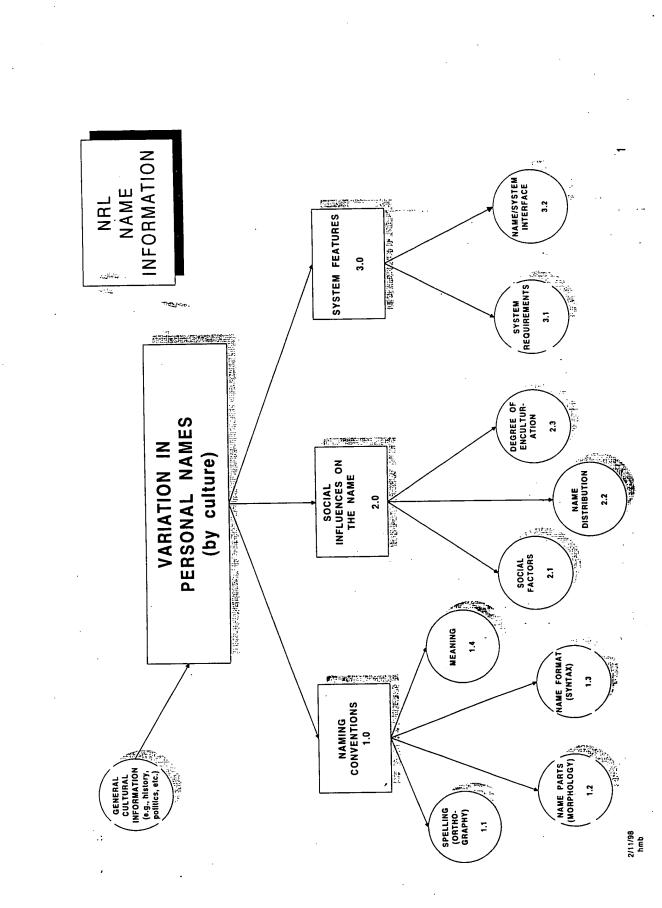

Pre-defined COB category relationships will provide a definition of the values that appear in the COBPROX Data Store.

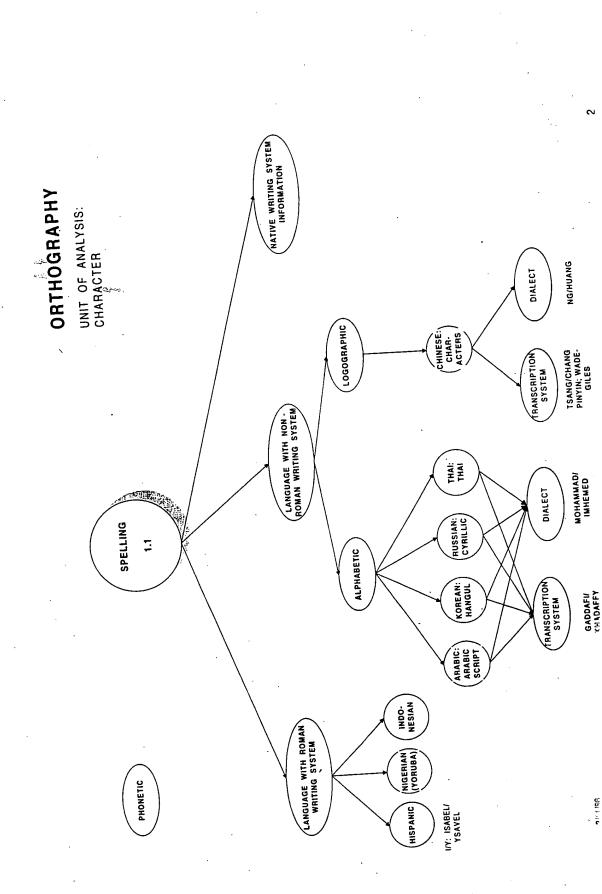

#### 4.18.5. Function

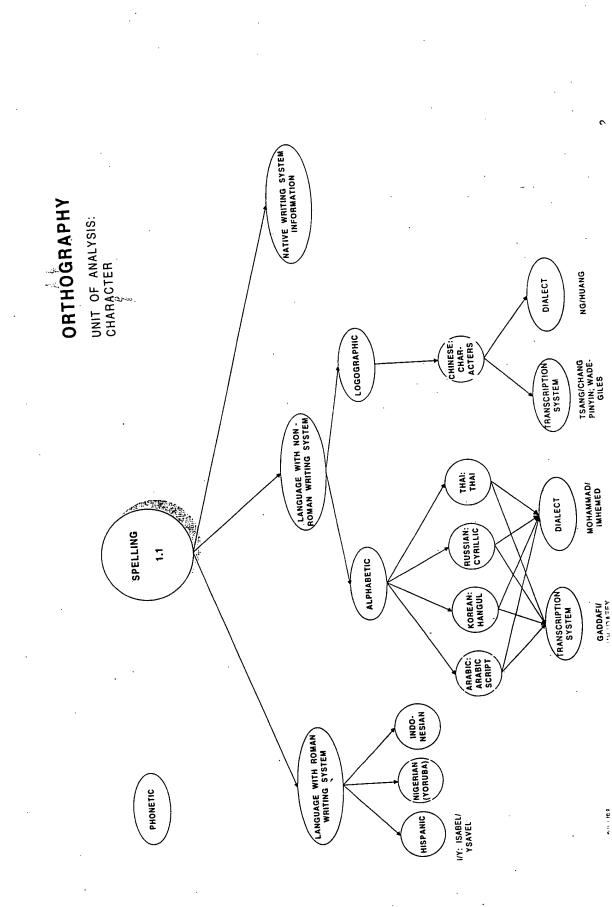

These COB categories will provide information about COB relationships that will contribute to determination of the Composite Score in the Arabic Filter and Sorter.

Automated Data Understanding Application Area:

Abstract

This paper describes a two-year research effort to incorporate phonological information into automated name searching. Specifically, names represented by standard roman characters are automatically converted to multiple phonetic representations, based on sets of regular expressions that relate character strings to predictable sounds or sound sequences using a widely accepted phonetic notation system, the International Phonetic Alphabet. Names are retrieved when there is an intersection of the regular expression of the query name with regular expressions of names in a preprocessed database. Additional similar names can be retrieved based on the articulatory characteristics of the sound segments contained in the query and database names.

### 1.0 Introduction

Variation in the spellings of names is a persistent issue in the area of automated name searching in large databases (Hermansen, 1985). In general, the source of spelling variation of names can be analyzed and explained a posteriori. Predicting any individual spelling, however, remains problematic. Sources for spelling variation include: keyboardbased data entry errors (e.g., hitting the wrong key: Genning for Henning), syntactic variation (e.g., out-of-sequence given name and surname such as Richard Thomas for Thomas Richard), morphological variation (e.g., truncated strings such as Rich or R for Richard) and semantically-based variation (e.g., nativizations such as Goldwater for Goldwasser). Of interest in the current paper is variation due to orthographic conventions (e.g., English can represent the same sound in more than one way, as in Stephen ~ Steven) and articulatory variation (e.g., the p in Thompson is a predictable spelling of Thomson based on principles of articulation). While there are multiple sources of name variation, this paper will present evidence 1) that the inherent ambiguity in the English use of roman characters can be mitigated by multiple mappings to unambiguous phonetic characters and 2) that phonologically-similar names can be retrieved through the analysis of sounds into their articulatory features (i.e., place and manner of articulation). It is based on research conducted from September of 1995 through the present.

### 2.0 Statement of Problem

Character-based name searching relies on spelling as the basis for calculating distance between the query name and the database name. While spelling using roman characters is not unrelated to pronunciation, the relationship between the two is often inconsistent (Cummings 1988), and the orthographic information (i.e., conventions of the spelling system of a language) is at times misleading. Thus, one spelling may map to multiple pronunciations: Lutz can be pronounced to rhyme with puts, cuts or shoots, and at least several additional non-English pronunciations are possible. The converse, of course, is also the case: there may be a number of ways of representing a single pronunciation: Lewis and Louis, for example, are usually pronounced identically by English speakers.

Character-matching techniques assume a reliable relationship between the orthographic system and the pronunciation. This assumption is flawed because the *goodness of fit* between orthography and pronunciation, especially for English, is *many-to-many*, that is, a given roman character can stand for more than one sound, and an individual sound may be represented in more than one way in the spelling system. Thus, the sound  $\{\Pi^i \text{ can be written as } f(Frank), ff(Taffy), ph(Phillip) \text{ or even } gh(Rough)$ . Conversely, the gh digraph may represent the [f] sound of Rough, be silent (Dough), or represent [k] (in some pronunciations of McClaughlin), [h] (in Monagham), [g] (in McGhee) or [gh] (across syllable breaks, as in Bighouse).

While much name variation can be traced to non-phonological issues, including syntax (order of name segments), aliases (John Doe for John Dillinger), morphological issues (Peg for Margaret) or data entry errors, many name variants can be traced to the relationship between orthography and pronunciation. Orally transmitted names, for instance, are especially prone to guesses on the part of the transcriber as to the "official" (i.e., legal) spelling of an individual's name. Language contact can account for some spelling variants as well (French Beauchamp and Anglicized Beecham), as can transcription from non-roman character sets (Wachmi and Ouakhmi, Xie, Hsieh and Sye) and sound change over time (e.g., Leigh is now pronounced the same as Lee).

Additionally, regular (i.e., predictable) processes of speech produce variability in how a name may be written. Thus, the presence of the letter p in *Thompson* is an artifact of poor articulatory timing as the articulators move from a nasal [m] to an oral [s]. (The variant spelling *Thomson* reflects a more etymologically justified spelling.)

### 3.0 Name Representation: Spelling

LAS has been investigating the feasibility and utility of incorporating information about the pronunciation of characters into the automated name searching process. The researchers considered a number of options, including an acoustic-level of representation and character-based rules, and determined that searching of character-based databases could be enhanced to include predictable language-based information about character-to-

Square brackets indicate that a sound is being represented, rather than a spelling.

A

sound mappings. Specifically, LAS recommended the use of the stock of phonetic symbols known as the International Phonetic Alphabet (IPA), widely used by linguists to represent the inventory of sounds used in the world's languages, and officially adopted by the International Phonetic Association (Laver, 1994). The IPA uses a closed set of symbols to transcribe speech in ways that are interpretable unambiguously by linguists, regardless of the language being described. (See Appendix A.) For example, the symbol [1] (placed between brackets to indicate that it represents a sound rather than a letter) always stands for a voiceless labiodental fricative, as in English thigh, while [] always stands for the equivalent voiced labiodental fricative, as in English thy. Thus, IPA disambiguates the English orthographic pattern of using th to stand for either sound: thigh [\$\pmu\_aj] versus thy [aj]. A name such as Gaither, of course, might be pronounced with either of these sounds, and would thus have two IPA representations, one for each pronunciation: [ge↓r] versus [ger]. There is international agreement by members of the International Phonetic Association, founded in 1889, as to the interpretation of IPA symbols. A reevaluation of the stock of symbols and special diacritic marks took place at the 1989 IPA Convention in Kiel, and the efforts of the Association have resulted in the unambiguous mapping of sounds onto IPA symbols that transcends individual speakers or languages (Laver, ibid.).

### 4.0 Mapping Spelling to Sound

The issue of how to predict pronunciation of names from orthography is far from trivial. Two key considerations include that:

- pronunciations of proper names are far less uniform than pronunciations of other vocabulary. The pronunciation of the noun dough is more-or-less fixed in English, despite the fossilized spelling that can be traced to an earlier pronunciation: The pronunciation of the name Lough is far less certain: individuals named Lough may well vary in their pronunciation of the family name and, even if all families named Lough could reach a consensus, there is no assurance that those unfamiliar with their consensus would guess that pronunciation. Additionally, some names retain old spellings that map to modern pronunciations in highly improbable ways (e.g., British Cholmondeley is commonly pronounced the same as Chumley). Claims of "correct" pronunciations carry little weight in terms of name searching; and:
- orthographies are language-specific. The pronunciation of the letter x regularly maps to [ks] and [z] in English (Alexander, Xenia), is regularly silent word-finally in French orthography (LaCroix), stands for the velar fricative [x], or [s] in Spanish (México, Xochimilco), and a [dz] or [] in Albanian (Hoxha). Additionally, standardized transcription systems from non-roman systems to roman exploit the letter x to stand for other, non-English sounds (e.g., Chinese Xie, Greek Xristos). Finally, any name may be nativized to fit the "borrower" language: spellings of non-Anglo names may be pronounced according to English orthographic conventions (e.g., French Duquesne pronounced [dukwzni].)

### 5.0 Writing IPA Conversion Rules

IPA is an effective notational system for representing pronunciation. LAS has written sets of rules that relate spellings to sounds. The rules are language-based, with sets of rules operating for Arabic, Mandarin Chinese, Hispanic and Anglo names. The rules assume:

- 26-character sets of roman letters, absent all diacritic markings, including accent marks or tone indicators;
- English speakers, either naïve or expert in the language of origin;
- one spelling can map to multiple pronunciations.

The rule sets were written to specific development databases made of single name elements, either surname or given, and taken from a variety of sources, including the U.S. Census list of the most frequent names in the U.S. and large U.S. databases of names from other countries. The names were manually tagged as "Arabic", "Mandarin Chinese", "Hispanic" and "Anglo", where "Anglo" was loosely interpreted to include Western European Germanic names (including Dutch and German). A team of linguists used a variety of sources to determine possible pronunciations, including native speaker knowledge and textual information (e.g., Cummings, 1988, Hanks and Hodges, 1989, 1990, Symonds, 1986). In general, rules were written broadly in order to ensure that most plausible pronunciations were captured. The Arabic and Mandarin Chinese rules included transcription variation (e.g., Chinese pinyin, Wade-Giles and Yale conventions of rendering Chinese names into roman script, as in Xie/Hsieh/Sye). The sample Anglo rule below is interpreted to mean that the letters sc preceded by anything and followed by the letters le can be pronounced as [s] or [sk] (e.g., Muscle and Mosclin):

sc/ anything \_\_\_\_  $le \rightarrow [sk?]$ 

Rules were implemented using standard regular expression notation. The following table shows a sample query and the names returned from a data file containing the 88,799 most frequent surnames from the U.S. census:

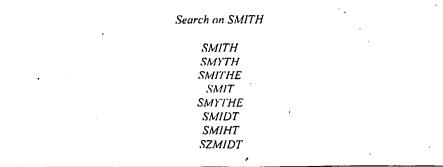

Figure 1 Search on name SMITH

e-30.

03/06 '98 12:43

As an example of the advantages of matching on IPA, consider a query on the name Lee. Converted to the IPA string [li], exact matches with numerous spelling variants are automatic, including Leigh and Li. Typical character-based matches will fail to retrieve Leigh or Li, since the percentage of character overlap is minimal. Conversely, a standard index matching system such as Soundex will categorize Lee and Li identically, but will still miss Leigh, given the presence of a salient letter (g), and will retrieve a large number of names of low relevance, including Lu, Liao, Low, Louie. Luhoya and Lehew.

### 6.0 Phonological Processes

In addition to predictable spelling variation, rules were written to account for predictable articulatory processes (MacKay, 1987; Wolfram and Johnson, 1982). For example, the variant spellings of Thomson ~ Thompson, Simson ~ Simpson, Demsey ~ Dempsey, etc. can be accounted for by regular movement of the velum (i.e., the soft palate) from a bilabial nasal [m] to an oral [s]. Production of an intrusive bilabial oral [p] is entirely a result of the timing of the movement from nasal to oral articulation. LAS incorporated likely articulatory variation into the IPA rule sets. Thus, a query of the name Thomson will retrieve the variant Thompson as an exact match.

### 7.0 Testing the Rule Sets

To test the net effect of the Orthography-to-IPA rules, LAS conducted a controlled test of the rules by randomly selecting 157 test names from a database of 55,545. The database contained names that were from sources identified as Arabic, Mandarin Chinese, Hispanic and Anglo (again, broadly defined). A native speaker of educated standard American English was asked to record the 157 test names using pronunciations of his choosing. The audio recordings were played for native speakers of American English, who were asked to write one or more "likely" spelling for each name. LAS elicited 3,689 variants in all by playing the recordings to native speakers of American English. The variant spellings were then used as test query names to calculate the retrieval rates of the original name spellings. Overall, 69% of all variant spellings were retrieved by the IPA rules. However, qualitative analysis of the results showed that approximately 23% of the variant names not retrieved were due to perceptual mishearings of the recorded names. For example, the variant spellings of the test name Baughn predictably included Bahn, Baun, and Bonn, and the IPA Conversion Rules succeeded in mapping all to the original test name spelling. However, a fourth elicited spelling, Vaughn, was not predicted, and the IPA Conversion Rules did not map it to Baughn. The mishearing of [v] for [b] is not unusual, given the acoustics shared by the two sounds. The IPA Conversion Rules, which include regular articulatory variants such as Thomson/Thompson, were purposely not intended to retrieve perceptually similar names during the current phase of research.

### 8.0 Fuzzy Matches: Articulatory Similarity

At the heart of the research has been an effort to improve the automatic name searching process by retrieving names that are similar to the query name. The IPA Conversion Rules are able to capture a good deal of name variation that can be attributed to orthographic sources, whether intralingual (e.g., Leigh/Lee) or interlingual (e.g., transcriptions to roman orthography from Chinese: Xie ~ Hsieh ~ Sve). An additional goal has been to retrieve names that are not phonologically identical to the query name, but that a careful analyst would like to consider before abandoning a search. Thus, while spelling variants of the name Benke include Behnke and Benck, the analyst might want to consider names that seem phonologically close to the query name without being a predictable variant (e.g., Benge, Bankey and perhaps even names like Penke. Panke or Benische). While most search algorithms permit fuzzy matches, these are invariably based on calculations of number of characters shared. From the perspective of character matching, the letter h is as different from the p as it is from x, y or z. Thus, to permit retrieval of Penke for Benke is to require retrieval of any name that differs from the query by the first character, including Xenke, Yenke and Zenke. This clearly does not follow any phonologically reliable principle, and significantly reduces the efficiency of automatic retrieval. Even indexed systems, such as Soundex, group letters as either co-indexed or unrelated. Thus, while Soundex is often called "phonetic" because it groups letters that share some phonological characteristics, it cannot compare the degree to which two sounds, or indeed two names are related: it lacks granularity. Thus, Soundex would treat Benke, Penke and Panke as identical rather than similar. Soundex would exclude Bentsche from the group because of the letter t in the spelling, in effect treating Bentsche as being equally distant from Benke as from Smith.

It is clear, however, that sound segments can be analyzed in terms of their articulatory characteristics, and that some sounds fall into natural categories, such as vowels and consonants. Properties of sounds have been described in detail by a number of linguistic analyses according to place and manner of articulation (e.g., [p] and [b] are both articulated at the lips by complete blockage of the air flow and sudden release of pressure). One of the best known descriptions of phonetic classification is that of the American linguists Chomsky and Halle (1968). All the distinct sounds of American English can be described using 15 distinctive features (see Appendices B and C). By classifying sounds according to these distinctive features, a fairly clear picture emerges of how close any two sounds are to one another. Thus, [p] and [b] differ by just one feature, voicing, while [p] and [f] differ by three and [p] and [v] by four. In general, articulatory distance can be counted in terms of how many articulatory characteristics sounds share.

LAS created a file of feature differences between pairs of sounds, essentially mapping phonetic features onto IPA notation. By relaxing the threshold of allowable differences, increasingly distant sounds are retrieved. Thus, by permitting matches of IPA characters that are not exact matches, names are retrieved that are phonologically close. Even IPA sound-to-sound comparisons yield interesting sets of names for comparison. By relaxing

retrievals to include single feature differences, a search of the name Smith now brings back these additional names:

FAX:703-834-6230

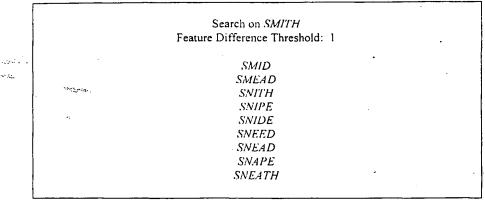

Figure 2 Fuzzy Search on Smith measuring Phonetic Feature Differences

Viewed in physiological terms, this is reasonable. Phonetic features refer to salient characteristics of articulation, so that differences generally reflect how likely it is that any two sounds would be articulated in place of another. There are numerous additional factors, of course, that ought to be considered in measuring how similar two names are to one another articulatorily.

### 9.0 Final Sorting of Names Retrieved

The names retrieved by searches on phonetic features may not all be of equal relevance to the query name. Additional factors are under consideration to sort names retrieved, based on a variety of phonological characteristics.

### 9.1 Sonority Level

The differences in phonetic features generally express the amount of effort needed to move articulators from one sound to another. The sounds [p], [t] and [k] form a natural class of voiceless stop consonants — identical in manner of articulation. All are extremely common in the world's languages, and are among the first acquired by children. They differ in place of articulation, and this is reflected in feature differences. However, manner of articulation is probably a better measure of energy expenditure than is place of articulation: voiceless stops are all extremely low in sonority, that is, the amount of energy needed to produce a sound. Vowels, on the other hand, require much more effort: they, in essence carry the sound wave. In order for feature differences to effectively measure level of effort required, differences should be weighted according to sonority level. In general terms, sounds fall into nine levels of sonority, with voiceless stops [p], [t] and [k] at the

low end and the vowels [] as in *father* and  $[\oplus]$  as in *fan* at the most sonorous end (Ladefoged, 1982). Sorts of names retrieved ought to consider the sonority value of sounds. This might be accomplished by weighting phonetic features or by a more complicated comparison of sonority level contours of names or syllables.

### 9.2 Syllabification

Additionally, in languages that time segments based in part on stress patterns, it is reasonable to compare stressed syllables to one another. In the following example, names have been aligned in terms of substrings, in this case corresponding to syllables:

Chester: 
$$\begin{bmatrix} \tau + \sigma \tau \rho \end{bmatrix}$$
  
Chesterion:  $\begin{bmatrix} \tau + \sigma \tau \rho \end{bmatrix}$   
Winchester:  $\begin{bmatrix} \omega & v & \tau + \sigma \tau \rho \end{bmatrix}$ 

Both in terms of articulatory effort (sonority) and psychological salience, it would be misleading to treat all three occurrences of the substring [t+] as equivalent: stress clearly must be included in the equation. LAS has written a syllabifier that automatically parses English IPA strings, including names, according to a set of rules. Future research will investigate the possibility of ranking similar names through analysis at the syllabic level. Syllabic level analysis has the strength of lining up comparable substructures of names. All syllables share the same internal structures (i.e., onset of the syllable, nucleus, and coda), and alignment by syllable enables meaningful comparisons of internal structures of names (where a period represents the syllable break):

$$\begin{array}{lll} \textit{Linda} & [\lambda & \nu & \delta \,] \\ \textit{Lisa} & [\lambda \, \iota \,\_ & \sigma \,] \end{array}$$

Note that in the above example, the coda (i.e., end) of the first syllable in *Linda* is filled by [n] but empty in *Lisa*, as indicated by the underscore. A meaningful comparison of the two names would compare the [n] of *Linda* to an empty coda rather than to the [s] in the onset (i.e., beginning) of the second syllable of *Lisa*.

### 9.3 Position in Name

Some weight ought to be given to absolute initial position in names. Many indexed systems, including Soundex, key names to the initial letter. This is, of course, problematic, since the initial letter may be silent or part of a digraph (e.g., Knox, Philip). However, indexing on the first sound, or at least considering the first sound as more significant than sounds in other positions may be warranted. This, like syllable-level comparisons, will probably be a factor in final sorting of names retrieved.

### 9.4 Non-Phonological Factors in Sorting of Names Retrieved

Certainly, it must be acknowledged that non-phonological levels of analysis may be critical to any useful definition of *similarity*. Morphological units – word parts that may contain

semantic information, including prefixes and suffixes — such as Mc-, -ton, and -sky are likely sources of variations. Thus, Lubin and Lubinsky are critically related (in terms of their roots), while Lubin, Rubin and Lupine are very close in terms of articulation. The morphological factor could be handled efficiently with a look-up list of morphological elements, but this remains outside the current scope of this project.

Similarly, orthography itself might play a useful role in the final sort of names retrieved. The following names retrieved for a fuzzy search on the name *Bucket* have been sorted using a simple sort on letters.

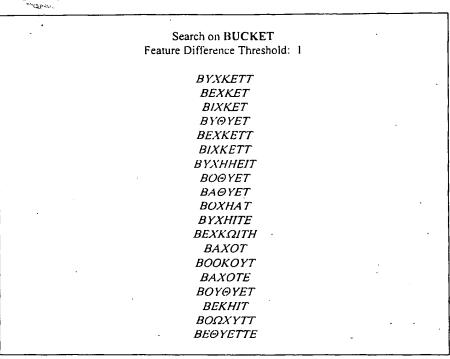

Figure 3 Search on Bucket Sorted by Spelling

Current plans are for a final ranking of names retrieved based on a combination of factors, including number of syllables, stress, weighting of features by sonority levels and name-initial segments.

### 10.0 Conclusions

In sum, automatic name searching can benefit in three ways from incorporation of phonological information:

· 10,

FAX:703-834-6230

- leveling differences due exclusively to orthographic mapping:
- leveling differences due to predictable phonological processes, such as intrusive
- retrieving additional names that contain phonologically similar sounds to those of the query name.

Having retrieved phonologically relevant names, a phonologically-enhanced name search engine can then sort names using a multiple factor weighting scheme.

LAS views this technology as extremely promising, offering a tool to enhance current automatic name searching, increasing chances of retrieving name variants that characterbased systems miss by retrieving and sorting names in a phonologically principled way.

Appendix A: Descriptions of IPA Symbols

Phonetic symbol	Description	Example
p	voiceless bilabial stop	p in the English name Peter
b	voiced bilabial stop	b in the English name Buddy

0	voiced alveolar flap	tt in the English name Ritter
16	voiceless retroflex stop	as in the Arabic name Tariq
<del></del>	voiced retroflex stop	as in the Arabic word difda' (frog)
•	voiceless retroflex fricative	as in the Arabic name Sabir
(f)	voiced retroflex fricative	as in the Arabic name Dhafir
2	voiced retroflex nasal	Marathi (India)
Û	voiced retroflex lateral approximant	Marathi (India)
64	voiced retroflex flap	d as in Hindi dal (lentil stew)
•	voiceless palato-alvoelar fricative	sh in the English name Sheila
<u>(·</u>	voiced palato-alveolar fricative	z in the English word azure
Ø	voiceless alveo-palatal fricative	x as in the Chinese name Xia
	voiced alveo-palatal fricative	i in the Polish word ile
I.	voiceless palato-alvoelar affricate	ch in the English name Charlie
dC∙	voiced palato-alveolar affricate	j in the English name Jennifer
0	voiced palatal nasal	■① in the Spanish word Do■②a
<u> </u>	voiced palatal lateral approximant	II in the Spanish word calle (street)
k	voiceless velar stop	k in the English name Kim
g	voiced velar stop	g in the English name Gary
X	voiceless yelar fricative	x in the Spanish name Jose
	voiced yelar fricative	g in the Spanish word luego (later)
-0	voiced velar masal	ng in the English name Bing
	VUICCU VEIAI IIASAI	ng in the English name bing

Phonetic symbol	Description	Example
€	voiceless velar lateral	I in the Polish Walesa
K	voiceless labio-velar approximant	wh as in the English name White (for
		some speakers)
w	voiced bilabial approximant	w in the English name Wayne
q	voiceless uvular stop	as in the Arabic name Qasim
G	voiced uvular stop	Eskimo and Tehrani Persian
4	voiceless uvular fricative	ch as in the German word Buch
<b>8</b>	voiced uvular fricative	r in some Parisian pronunciations of the
		French name RenJe
Ñ	voiced uvular nasal	n in the Eskimo word eNima (melody)
R	voiced uvular trill	r in the French name RenJe .
0	voiceless pharyngeal fricative	h as in the Arabic name Muhammad
E>	voiced pharyngeal fricative	as in the Arabic name Sa'ad
و()	voiceless glottal stop	tt as in the English name Sutton or the
		word mitten
h	voiceless glottal fricative	h in the English name Henry
D	voiced glottal fricative	h as in English between voiced sounds,
		as in the word manhood
у.	high front rounded vowel	u in the French word lune (moon)
•	high central unrounded vowel	as in the Russian word s⊕n (son)
*	High central rounded vowel	u as in the Norwegian hus
0	high back unrounded vowel	u as in the Japanese name Kazu
u	high back rounded vowel	ou as in the French word tout
₽ı_	upper mid-front rounded	ö as in the German name Sch'nfeld
7	upper mid-back unrounded vowel	as in the Shan (Burma)word 'ko (salt)
0	upper mid-back rounded	o as in the English name Mona
<u> </u>	semi-high front unrounded vowel	y as in the English name Lynn
3	lower mid-front unrounded	e as in the English name Deborah
*	lower-inid front rounded vowel	oeu as in the French word oeuf (egg)
ຄ	lower-mid back unrounded vowel	u as in the English name Tupperman
9	lower-mid back unrounded	o as in the English name Ford.
F	open front unrounded vowel	a as in the English name Hal
0	open central unrounded vowel	a as in the Portuguese word para (for)
<u> </u>	low front unrounded vowel	a as in the French word patte (paw)
α	low central unrounded vowel	å as in the French name Delâtre or the
		word p>te (paste or dough)
_ <u> </u>	low back rounded vowel	o as in the British English word hot
*	mid central unrounded vowel	e & a as in the English name Belinda
<u> </u>	semi-high back rounded vowel	u as in the English name Butch
е	upper-mid front unrounded	a as in the English name Mable
_ <u>i</u>	high front unrounded vowel	first e in the English name Pete
ষ	rhotacized mid-vowel	ea as in the English name Heather

### Appendix A: Descriptions of IPA Symbols (Continued)

honetic symbol	Description	Example
ίØ	voiceless alveo-palatal affricate	j as in the Chinese name Jin
.f <u>Ω</u> ,	voiceless aspirated alveo-palatal affricate	q as in the Chinese name Qiu
ts	voiceless unaspirated dental affricate	ts as in the Chinese name Tsang
ts'	voiceless aspirated dental affricate	c as in the Chinese name Cao
Ø	bilabial click	as in Southern Bushman languages
- Paginero	dental (alveolar) click	as in Bushman
!	palatal click	as in Bushman
<b>-</b> &	palato-alveolar click	as in Hottentot
0	alveolar lateral click	as in Bushman, Zulu

يو. در

### Appendix B: Description of Phonetic Features

### A. Major class features:

I. Syllabic

Forms the central peak of a syllable. Vowels are usually +syllable, consonants are usually -syllable, but some (like [1]) may be syllable (as in "riddle")

2. Sonorun

Minimal constriction in the mouth. Vowels, as well as [n], [m], [r], [t], [w] are all +sonorant. Most other consonants are -sonorant.

3. Consonantal

Obstruction along a central point in the mouth. All English sounds except vowels and glides ([w] and [y]) are a consonantal.

### B. Manner of Articulation Features:

4. Continuant

Continued air movement through the mouth during sound production. This feature contrasts fricative sounds like [ f ] and [ v ] with non-continuants like [ p ] and [ b ].

5. Strident

Narrow obstruction through which air escapes, producing hissing or "white noise". [s], [f], [v] and the sounds in church and judge are +strident. This is the most acoustically-based feature in this list.

6. Delayed Release

Gradual release of air. In English, it is used to distinguish the sounds in church and judge from  $[\iota]$  and [d]

7. Nasa

Soft palate at the back of the mouth is lowered and air goes into nose. In English,  $\{n\}$ ,  $\{m\}$  and  $\{2\}$  (the final sound in king) are +nasal.

8. Lateral

Side(s) of tongue lowered so that air escapes along side, as in English [1].

### C. Place of articulation:

9. Anterior

Obstruction of mouth anywhere from gum ridge forward to lips. English [ p ], [ b ], [ m ], [ f ], [ v ], and [  $\Im$  ] (as in the) are all +anterior.

10. Coronal

Front of the tongue raised. The sounds  $\{t\}$  and  $\{d\}$  are +coronal. Sounds like  $\{k\}$  and  $\{g\}$  are -coronal.

11. High

Body of tongue raised. [j] (as in yellow), and the vowel [ H] (as in feet) are -high.

### Appendix B: Description of Phonetic Features (Continued)

- Low
   Body of tongue lowered. The vowels [ → ] as in back and [ 8] as in father are +low.
- 13. Back

  Body of tongue moved back. The sounds [k] and [g] and the vowel [u] as in boot are +back.
- 14. Tense

  Root of tongue muscle tensed. The vowel [ H ] (as in feet) is +tense. The vowel [ H ] as in fit is tense.
- 15. Round

  Lips pursed or rounded. English vowel [u] (as in boot) is +round, while [ \* ] (as in beet) is -round.

Phonetic Features	l p l	b	[f]
syllabic	-	-	-
sonorant	-	-	-
consonantal	+	+	+
anterior	+	+	+

### 1.0 Introduction

 $\Phi^{\bullet}_{i}(\lambda)_{i,j}$ 

This narrative describes the algorithms and techniques used by the Name Search - Technology Demonstration System (NS-TDS). It is the English-language version of the C++ source code that was used to develop the system. There are three major sections, covering NS-TDS support files, building the data base and performing a query. Each section relies on the contents of the previous section, so to effectively understand the system, this document should be read from beginning to end.

This narrative is tied to the source code through the use of paragraph numbers and comment lines. That is, whenever a block of code implements a technique or algorithm described in this document, a comment line has been inserted referencing the paragraph number. Comment lines are in the format, "// narrative paragraph number, x.x", where "x.x" stands for the paragraph number. If a block of code refers to more than one narrative paragraph, additional comments are added as separate lines.

### 2.0 Support Files

NS-TDS is a data-driven application dependent on a number of files that encapsulate years of computational linguistic research. These files represent the heart of the system and are essential to understanding how the primary algorithms work. This section of the narrative introduces these files by describing their purpose, contents and use.

### 2.1 Name Classifier Tables

TDS classifies the culture of a name as either Arabic, Chinese, Hispanic or "Other" (the default) by statistically analyzing its spelling. This analysis is accomplished with the aid of the following culture specific statistical distribution tables:

### 2.1.1 Digraph Score

Digraphs are contiguous letter pairs formed by parsing a name bracketed by a beginning and an ending boundary. For example, the name "FRED" consists of five digraphs: "#F", "FR", "RE", "ED" and "D#", where the symbol "#" represents a name boundary. In this table, digraphs that are clear indicators or contra-indicators of a particular culture are stored with a relative score. NS-TDS uses culture-specific tables to show the statistical likelihood of a particular digraph occurring in the applicable culture. For example, the digraph "QA" occurs almost exclusively in Arabic names, whereas the digraph "FM" almost never occurs in Arabic names. In the Arabic digraph table, "QA" is associated with a high positive score, and "FM" is associated with a low negative score.

### 2.1.2 Trigraph Score

Trigraphs are contiguous letter triplets that, for the purposes of TDS, are limited to the beginning and ending trigraphs. For example, the name "FRED" consists of the trigraphs "#FR" and "ED#". As with digraphs, NS-TDS uses culture specific tables to show the statistical likelihood of a particular trigraph occurring in the applicable culture.

### 2.1.3 Name Stop List

While generally good indicators of culture, digraph and trigraph distributions can erroneously classify specific names. For example, the name "BARKER" is identified as Arabic because it contains common Arabic letter patterns. The Name Stop List tables were implemented as a stopgap fix to this problem. For each culture, there is a Name Stop List table that contains a name along with a score that is either very positive (set to 2000) or zero (0). A high score means that name belongs to that culture; a score of zero means that the name does not belong there. So, "BARKER" is in the Arab Name Stop List with a score of 0.

The information in these tables is repeated for each culture and name part (i.e., given name or surname). For example, the following tables exist for Arabic:

agdi.dbf	Arabic digraph scores
agtri.dbf	Arabic trigraph scores
asdi.dbf	Arabic digraph scores
astri.dbf	Arabic trigraph scores

agnames.dbf Arabic given name stop list
asnames.dbf Arabic surname stop list

There are similarly named tables for Chinese starting with the letter "c" and tables for Hispanic starting with the letter "h".

### 2.1.4 Phonetic Rules

In order to convert the spelling of a name into a phonetic representation, NS-TDS consults several rule files. They contain records that consist of search parameters based on spelling and replacement regular expressions based on International Phonetic Alphabet (IPA) characters. Take the following rule, for example:

Boundary, "KN", Vowel, "(kn|kan|n)

It says that if the letter string "KN" is found at the beginning of a name ("Boundary") and is followed by a vowel, replace it with the IPA string, "(kn|kan|n)", where "|" indicates "or". The replacement string indicates that there are three possible pronunciations: [kn] or [kan] or [n]. (The use of square brackets is standard phonetic notation to indicate sounds rather than spelling). The spelling of a name is run through the rules until all characters are replaced with regular expressions. The name "KNOX" thus results in the regular expression (kn|kan|n)(a)(ks).

NS-TDS uses eight rule sets. For each of the four cultures (Anglo, Arabic, Chinese and Hispanic), there is a single vowel rule set and a multiple vowel rule set. The one vowel versions level all vowels to an [a] and produce fewer variations They are used for retrieval. The multiple vowel versions contain three basic vowel sounds, [a], [i] and [u], and are used in the ranking of retrieved names, since they are more precise than single-vowel rankings.

### 2.1.5 Simplified Phonetic Rules

One additional phonetic rule file is maintained to aid in the filtering process. It is a cross-reference file between all of the possible replacement strings in the single vowel rule sets and a simplified version of the replacement string. It is "simplified" in the sense that all unbalanced "ors" become balanced. For example, the replacement string (kn|kan|n) is "unbalanced" in that the possible pronunciations can contain one, two or three sounds. The simplified version is, (k?)(a?)(n), where "?" means that the sound is optional. The simplified string allows TDS to compare two regular expressions that may generate thousands of possible pronunciations with one calculation, thereby improving performance dramatically. Note that the simplified strings sometimes generate more possible pronunciations than the original replacement string, but never fewer. The additional pronunciations are handled adequately by the Ranker (see Section 4.5.1). Currently, this file is named tds.simp\_rul.

### 2.1.6 Leveled IPA Matrix

Generating retrieval keys requires the creation of leveled IPA variant strings. That is, similar sounds (i.e., [s] and [z]) are treated as a single set. NS-TDS uses a cross reference file to define the set relationships. It is currently called, grouparray.dat.

### 2.1.7 Feature Difference Matrix

One of the key components of TDS is the ability to calculate a phonetic score when comparing two names. When comparing individual sounds, the calculation weights the difference between two sounds based on a *feature distance.matrix*. This matrix consists of all combinations of two IPA characters and a score between 0.0 and 1.0 representing their phonetic proximity to one another, as defined by articulatory measures of similarity. It also contains records that represent the insertion or deletion of an extra sound. For example, the score assigned to the replacement of a [t] with a [d] is lower than the score assigned to the replacement of a [t] with a [k]. Further, inserting a vowel is given a lower score than inserting consonant such as [t] or [k].

The scores contained in this matrix reflect penalties. That is, higher scores mean that the sounds are further apart. All of the scores are based on linguistic principles of articulation, and reflect the number and type of phonetic features that cause the sounds to be different.

4".12.

### 3.0 Building the NS-TDS Data Base

In order to search a large number of names quickly, NS-TDS uses a data base of name information and indices. This data base is built by a program hereafter referred to as the *Data Loader*. This program takes as input a text file of names that are preceded with a group ID. The group ID is a minor component of TDS that was implemented to facilitate an independent evaluation by ORD.

Building the data base consists of two major steps. First, the names are pre-processed to generate the information needed by the retrieval, filtering and ranking algorithms. This pre-processed data is stored in temporary tables that are subsequently turned into the NS-TDS data base and indices. The following paragraphs describe this process in detail. Where appropriate, examples are used to make the description easier to understand.

### 3.1 Pre-Process Names

All names are pre-processed to ensure validity (see 3.11) and to gather the information necessary for retrieval, filtering and ranking. This process shares many of the components used to pre-process a query name during an NS-TDS search.

### 3.1.1 Edit the Name

Input names are provided to the Data Loader in a text file and are edited according to the following specifications: Positions 1 through 6 must contain a group ID, where the first character must be a digit or the letter "Z". All other characters must contain a digit. Position 7 must be blank. Positions 8 though 37 contain the name and can only consist of upper case letters or an apostrophe. Furthermore, the name must be at least 2 characters in length and no longer than 30 characters. Any records that fail to follow the prescribed format are rejected and written to an error log, along with an appropriate message.

### 3.1.2 Classify the Name

The spelling of the name is statistically analyzed to determine the probable culture (Arabic, Chinese, Hispanic, or "Other"). This analysis is accomplished with the aid of the name classifier tables.

First, the name is parsed into digraphs (contiguous letter pairs) and beginning and ending trigraphs (contiguous three letter triplets) (see 2.1.1 and 2.1.2). Next, the digraphs and trigraphs are located in the appropriate classifier table to obtain the individual score. All of the scores are summed to obtain a total score. This process is repeated for all cultures.

Then the Name Stop List tables for each culture are checked. If the name is found in one of the tables, the associated score is returned ("2000" means in the culture, "0" means not in the culture). If the name is found, the previously calculated culture score is replaced.

Finally, each score is compared to a culture-specific threshold. If no scores exceed the culture threshold, the name is classified as "Other". If one score exceeds the appropriate threshold, the name is classified accordingly. If more than one score exceeds the culture threshold, the highest score is chosen and that culture is returned. If there is a tie (very unlikely), the culture is chosen

alphabetically with Arabic first followed by Chinese and then Hispanic. It is important to note that an input name will receive only one classification.

### 3.1.3 Generate 1 Vowel Regular Expressions

In this step, the spelling of the name is run through the spelling-to-IPA phonetic conversion rules, to generate a regular expression that represents all of the possible pronunciations of the name. Every name is run through the single-vowel Anglo phonetic rule set, which is the default/generic rule set. If the name was classified as Arabic, Chinese or Hispanic, it is also run through the appropriate single-vowel rule set for that culture, generating a second IPA regular expression.

### 3.1.4 Generate Simplified Regular Expressions

Using the simplified phonetic rules, an simplified regular expression is generated. The expression is encoded into compact byte representations to make further calculations faster. As before, if the name was classified as Arabic, Chinese or Hispanic, a second simplified regular expression is generated according to the appropriate rule set.

### 3.1.5 Generate 1 Vowel Variants

Using the generated regular expression, a list of possible IPA variants is generated and added to a temporary table of variants for all input names. As an example, the name "KNOX", which generates the regular expression (kn|kan|n)(a)(ks), generates the following variants: [knaks], [kanaks], and [naks]. The temporary table lists all variants, as well as the name that generated the variant. It used later in the data base build process.

### 3.1.6 Determine the Initial Consonants

The variants are then analyzed, to generate a list of all possible name-initial IPA consonants. For example, the name "KNOX" starts with the regular expression (kn|kan|n), which can have an initial consonant of [k] or [n]. Note that if the variant starts with an IPA vowel, the first IPA consonant is used to build this list. Thus the name O'NEIL would have [n] as the initial consonant. This information is used by the Ranker (see section 4.4.4 below).

### 3.1.7 Set the Initial Vowel Switch

Next, the variants are analyzed to determine if it is possible for the pronunciation of the name to start with a vowel. It is a three-way switch that indicates whether the pronunciation (1) can never start with a vowel, (2) can sometimes starts with a vowel or (3) always starts with a vowel. This information is used by the Ranker (see section 4.4.5 below).

### 3.2 Build Data Base and Indices

This step takes all of the information produced during pre-processing and builds the data base and indices used by TDS for retrieval, filtering and ranking.

### 3.2.1 Create Name Files

A name file is generated for all four cultures processed by TDS (Anglo, Arabic, Chinese and Hispanic). "Anglo" represents the default, and therefore all names generate an Anglo record; only those names that are appropriately classified generate records in the other culture name files. Each record in the name file contains: the spelling of the name, the simplified regular expression codes, the list of initial consonants, the initial vowel switch, the group ID and an internal unique ID.

The naming convention is a four-letter culture identification followed by the extension, "nam". Currently, the following name files are generated: angl.nam, arab.nam, chin.nam and hisp.nam.

### 3.2.2 Generate Leveled Variants

40.00

Using the variants generated during pre-processing and the leveled IPA matrix, a list of leveled variants is built. Furthermore, the input variants have duplicate contiguous characters removed. The IPA characters in "KNOX" generate the following numeric codes, based on sets of similar sounds: [k] = 5; [n] = 2; [a] = 0; [s] = 4; [z] = 4. (Note that [s] and [z] are both indexed as "4"; since they are similar sounds). The following unique leveled variants are generated: 52054, 502054 and 2054. Note that the number of leveled variants is usually less than the number of non-leveled variants. For each input name, the leveled variants are added to a temporary file that lists all leveled variants and the name that generated it.

### 3.2.3 Create Retrieval Indices

Retrieval indices consist of a unique sorted list of leveled variants. As with the name files, one index is generated for each culture. Each index is created by sorting and then *deduping*, i.e., removing duplicate forms from the previously-built temporary file of leveled variants.

The files produced by this step are named angl.idx, arab.idx, chin.idx and hisp.idx.

### 3.2.4 Create Index-to-Name Maps

Finally, a map file is created that cross-references all of the index records with the name records that generated the leveled variant. The retrieval index records contain a pointer to a map record. The map record contains a list of pointers to name records. This structure allows TDS to quickly scan the indices and generate a list of candidate names during retrieval.

The names of the map files are angl.vec, arab.vec, chin.vec, and hisp.vec.

### 4.0 Performing a Ouerv

The heart of NS-TDS is the ability to perform a query that returns a ranked list of results. This is done using five major steps: query pre-processing, exact phonetic search, similar phonetic search, initial ranking and final ranking. The following paragraphs describe these steps and their components in some detail. When appropriate, examples are used to make the descriptions easier to understand.

### 4.1 Pre-Process Names

The query name is pre-processed to ensure validity and to gather the information necessary for retrieval, filtering and ranking. This process shares many of the components used to pre-process an input name during the building of the NS-TDS data base.

### 4.1.1 Edit Name

After the user enters a query name via the user interface, it is edited according to the following criteria: The name can only consist of the 26 letters of the Roman alphabet or an apostrophe. Further, the name must be at least 2 characters in length and no longer than 30 characters. Errors are displayed to the user in a dialog box, along with an appropriate message.

### 4.1.2 Classify Name

If the user has specified that culture classification is automatic (the default), the spelling of the name is statistically analyzed to determine the probable culture (Arabic, Chinese, Hispanic, or "Other"). This analysis is accomplished with the aid of the previously described name classifier tables (see 2.1 above). If the user has overridden the default and manually specified a culture, this step is skipped.

The name is then parsed into digraphs (contiguous letter pairs) and beginning and ending trigraphs (contiguous three letter triplets). Then, the digraphs and trigraphs are located in the appropriate classifier table to obtain the individual score. All of the scores are summed to obtain a total score. This process is repeated for all cultures.

Next, the Name Stop List tables (see 2.1.3 above) for each culture are checked. If the name is found in one of the tables the associated score is returned ("2000" means in the culture, "0" means not in the culture). If the name is found, the previously calculated culture score is replaced.

Finally, each score is compared to a culture specific threshold. If no scores exceed the culture threshold, the name is classified as "Other". If one score exceeds the appropriate threshold, the name is classified accordingly. If more than one score exceeds the culture threshold, the highest score is chosen and that culture is returned. If there is a tie (very unlikely), the culture is chosen alphabetically, with Arabic first, followed by Chinese and then Hispanic.

It is important to note that an input name will receive only one classification. Further, if the classification is Arabic, Chinese or Hispanic, all further pre-processing will be performed twice (once for the default Anglo culture and once for the culture identified by classification or as manually specified by the user).

### 4.1.3 Generate 3 Vowel Regular Expressions

In this step, the spelling of the name is run through the multiple vowel phonetic rules to generate a state table that represents all of the possible pronunciations of the name in IPA form. Every name is run through the default Anglo phonetic rule set. If the name was classified as Arabic, Chinese or Hispanic, it is also run through the appropriate rule set for that culture generating a second state table. These will be used during the *exact* phonetic search (see 4.2).

### 4.1.4 Generate Multiple (3) Vowel Variants

Using the multiple vowel state table, a list of all possible IPA variants is generated. As an example, the name, "KNOX", which generates the regular expression (kn|kan|n)(a|u)(ks), generates the following IPA variants: [naks], [nuks], [kanaks], [kanaks], [knaks], and [knuks]. This list will be used to perform a brute force phonetic score adjustment on names that pass preliminary ranking (see 4.5).

### 4.1.5 Generate 1 Vowel Variants

Using the 1-vowel state table, a list of all possible one-vowel IPA variants is generated. As an example, the name, "KNOX", which generates the regular expression, (kn|kan|n)(a)(ks), generates the following variants: [naks], [kanaks], and [knaks]. This list will be used to generate retrieval and ranking information.

### 4.1.6 Determine the Initial Consonants

The single-vowel variants are then analyzed to generate a list of all possible initial IPA consonants. For example, the name KNOX starts with the regular expression, (kn|kan|n), which can have an initial consonant of [k] or [n]. Note that if the name starts with a vowel, the first IPA consonant is used to build this list. Thus, the name, O'NEIL would have [n] as the initial consonant. This information is used during ranking (see 4.4.4).

### 4.1.7 Set the Initial Vowel Switch

Next, the single-vowel variants are analyzed to determine if it is possible for the pronunciation of the name to start with a vowel. It is a three-way switch that indicates that the pronunciation (1) can never start with a vowel, (2) can sometimes start with a vowel, or (3) always starts with a vowel. This information is used during ranking (see 4.4.5).

### 4.1.8 Generate Leveled Variants

Using the appropriate one-vowel rule set, a temporary list of all possible IPA variants is generated. This list, along with the leveled IPA matrix, is used to build a list of leveled variants. Also note that duplicate contiguous characters are removed. For example, the IPA characters in KNOX generate the following numeric codes, based on sets of similar sounds: [k] = 5; [n] = 2; [a] = 0; [s] = 4; [z] = 4. (Note that [s] and [z] are both indexed as "4", since they are similar sounds). The following unique leveled variants are generated: 52054, 502054 and 2054. Note that the number of leveled variants is usually less than the number of non-leveled variants.

### 4.1.9 Generate Simplified Regular Expressions

Using the simplified phonetic rules, a simplified regular expression is generated. The expression is encoded into compact byte representations to make further calculations faster. As before, if the name was classified as Arabic, Chinese or Hispanic, a second simplified regular expression is also generated.

### 4.1.10 Initialize Search Parameters

The search parameters specified by the user or defaulted by the application are stored along with the query information. These parameters set thresholds for retrieval and filtering, and determine the weights given to individual ranking scores.

### 4.2 Exact Phonetic Match

An exact phonetic search is always performed by TDS. It is a quick search that retrieves names which share at least one possible pronunciation with the query name and passes them to the ranker. A search of the Anglo data base is always performed; if a non-Anglo culture was determined or specified by the user, the search is repeated for the appropriate culture.

### 4.2.1 Rétrieve Candidates

Each of the leveled variants generated by pre-processing the query name are used as a key to perform a binary search of the retrieval index, which is a set of unique leveled variants for the name data base. In the case of "KNOX", three leveled variant indices are retrieved: 2054, 502054 and 52054.

### 4.2.2 Retrieve Name Information

Using the index-to-name map files, all data base names and associated information that could possibly generate the leveled variants found above are put into a list. In the case of "KNOX", names such as "NOCKS", "NOX", "KNOCKS" and "NAUCHS" are returned.

### 4.2.3 Execute Exact Phonetic Match Algorithm

For each name retrieved, a regular expression is generated using the appropriate multiple-vowel rule set. Each of these is compared to the query's regular expression to determine if there is an intersection. In other words, the two expressions are evaluated to see if they can generate a matching variant. This evaluation is done by generating non-deterministic finite state tables and walking through each table until a match is impossible (i.e., the names do not match), or the end of both tables is reached (i.e., the names match). If the name passes this algorithm, it is placed in a list.

### 4.2.4 Pass Exact Matches to the Ranker

All names that pass the exact-match algorithm are sent to the Ranker, along with the information retrieved from the name file. In addition, the phonetic score is set to 1.0, which is the highest

possible score, and the pipe (rule set) that was used to retrieve the name is passed. Note that if a name was found to be an exact match under two cultures, it is included twice.

### 4.3 Similar Phonetic Match

A similar phonetic search is performed only if the user has requested it. Note that the default is to perform a similar search. It is slower and more thorough than the exact search, and retrieves names that sound similar (based on principles of articulation) to the query name to the ranker. A search of the Anglo data base is always performed; if a non-Anglo culture was determined or specified by the user, the search is repeated for the appropriate culture.

### 4.3.1 Scan the Retrieval Index

A complete scan of the retrieval index is performed, and each leveled variant is compared to the leveled variants generated by pre-processing the query. The comparison uses a standard edit distance calculation to determine how far apart two strings are. The algorithm determines the minimum number of edits (insertion, deletion or replacement of IPA characters) necessary to convert one string into another. A score is calculated by dividing the number of edits by the maximum length of the two strings and subtracting this fraction from 1 resulting in a score between 0.0 and 1.0. This score is compared to the retriever threshold, and those records with a score greater than or equal to the threshold are added to a candidate list.

### 4.3.2 Filter the Candidates List

This list is scanned and, if the name has not already been retrieved by the exact match algorithm, the simplified regular expression of the query name is compared to simplified regular expressions of all of the candidate names. This comparison uses a more linguistically sophisticated edit distance algorithm that takes into account the phonetic features of each sound. All edits are weighted according to the relationships stored in the Feature Distance Matrix, For example, the replacement of similar sounds that share most phonetic characteristics, like [s] and [z], are given a small penalty. The "cost" of replacements is determined by where and how sounds are articulated in the mouth and the "effort" required to produce one rather than the other. Similarly, some insertions and deletions of sounds are more costly than others (e.g., insertion of a [t] is more costly than insertion of a vowel, [a]). So, instead of computing the minimum number of edits required to convert one string into another, this algorithm calculates the path of least resistance. As with the retrieval calculation, a score between 0.0 and 1.0 is obtained by dividing the total penalty by the maximum length and subtracting this fraction from 1. This score is compared to the filter threshold, and those records whose score is less than the threshold are discarded.

Finally, it is important to note that because simplified regular expressions can generate more variants than the expressions they were derived from, it is possible for this score to be higher than expected, although it is impossible to obtain a lower score. This deficiency is corrected during ranking.

### 4.3.3 Pass Similar Matches to the Ranker

For all records that pass the filter algorithm, additional information is gathered from the name file via the index-to-name map. Also, the phonetic score of these names is set to the score

calculated during the filter edit distance calculation, and the culture pipe (i.e., rule set) that was used to retrieve the name is passed. This list is sent to the Ranker for initial scoring. Note that if a name was found to be a similar match under two cultures, it is included twice.

### 4.4 Initial Ranking

Names that pass the retrieval and filter stages via the exact or similar phonetic match searches are sent to the Ranker, along with the phonetic score calculated by the filter and all of the data built during the pre-processing stages (initial consonant, initial vowel, etc.). The ranker also knows which search (exact or similar) produced the return. It takes this information, calculates several other scores, applies weights to those scores based on the query parameters and produces a ranked list of names with combined scores. Initial ranking differs from final ranking in that it uses the phonetic score calculated by the filter. Final ranking, which is described below (see 4.5), performs a more exhaustive and exact phonetic score calculation.

### 4.4.1 Calculate the Spell 1 Score

Because spelling is a relevant factor in determining similarity of names, the Ranker is set up to consider spelling in its calculations in ranking of names passed to it. In the case of exact matches, for example, all phonetic scores are 1.0, but spellings can vary widely (e.g., "LI", "LEE", "LEIGH"). The Spell 1 score is a comparison of all the letters in the query name to all of the letters in the data base name. Each letter that matches contributes to the score, and no letter can be used more than once. Note that the position of the letter has no bearing of the score. So, the "K" in "KNOX" matches the "K" in "SACK". In addition, there is an option to bias the score so that letters on the left side of the query name count more than those towards the end. The "left-bias" factor defaults to true. A score is calculated by dividing the value of the matches (an integer, if left bias is not used) by the maximum length of the query and data base name and then subtracting this fraction from 1.0. This results in a score between 0.0 and 1.0.

### 4.4.2 Calculate the Spell 2 Score

The Spell 2 score works similarly to Spell 1, except that it uses digraphs instead of single letters. Digraphs are contiguous letter pairs formed by parsing a name bracketed by a beginning and an ending boundary. For example, the name "FRED" consists of five Roman character digraphs: "#F", "FR", "RE", "ED" and "D#", where "#" represents a name boundary. Digraphs build some contextual information into the calculation, with the result that "FRED" and "BRID", which share two non-contiguous letters, have a lower Spell 2 score than a Spell 1 score. Spell 2 uses the same left bias parameter and the same method to turn the calculation into a decimal number between 0.0 and 1.0 as Spell 1. Finally, the Spell 2 score contains a special adjustment for names that start with a vowel. For example, when comparing the name, "NEIL" to "ONEIL" and "SNEIL", the score for "NEIL" will be adjusted upwards by a small factor.

### 4.4.3 Calculate the Syllable Score

The Syllable score compares the number of syllables in the query name to the number of syllables in the data base name. Counting the number of syllables in a name is based on the spelling, and essentially says that a syllable occurs when there are one or more vowels in a row; preceded by a consonant or a word boundary. Adjustments are made for special cases such as, dipthongs (multiple consecutive vowels pronounced as two syllables) and "E" or "ES" at the end

of name which often does not produce a separate syllable. A score is produced by dividing the difference in the number of syllables between the query name and the data base name by the maximum number of syllables in the query or data base name and subtracting the resulting fraction from 1.0. This results in a score between 0.0 and 1.0.

### 4.4.4 Calculate the Initial Consonant Score

The initial consonant sound in names hold particularly prominent positions in determining similarity of names. The Initial Consonant score compares the first occurrence of an IPA consonant in the query name to that of the data base name. The consonants are compared based on the Feature Distance Matrix, producing a score between 0.0 and 1.0. For example, [s] and [z] will return a high score, whereas, [k] and [r] will return a low score. Note that the first consonant can be different as is the case with the name, "KNOPF", which could start with a [k] sound or an [n] sound. The algorithm compares all possibilities and returns the best possible score.

### 4.4.5 Calculate the Initial Vowel Score

The Initial Vowel score comes into play when both the query name and the data base name start with a vowel. If this is not the case, the initial vowel score is 1.0. Otherwise, the IPA vowel or vowels that start the names are compared and a score is returned based on the feature distances between them. The score is a decimal between 0.0 and 1.0.

### 4.4.6 Calculate the Culture Score

The culture score compares the culture of the query name as determined by the classifier or as specified by the user with the "pipe" (rule set) used to retrieve the data base name. So, if a name is classified as Arabic, and the name being ranked was passed to the ranker via the Arabic pipe, the culture score is 1.0. If the query culture does not match the pipe used to retrieve the name, the culture score is 0.0. This allows the Ranker to "bump up" names that share the same cultural identity, as in Chinese "CHIN" and "CHANG" (versus non-Chinese "CHAIN", for example).

### 4.4.7 Calculate the Final Score

The final or total score is an amalgamation of all of all the previous scores. NS-TDS maintains a set of parameters that allows the user to assign weights to each of the various individual scores. Note that in the user version, these weights are not modifiable. The weights are intended to be percentages, so that each factor is a decimal between 0.0 and 1.0 and the total adds up to 1.0. This is not a requirement, as the calculation recomputes the weights relative to one another.

So, to arrive at the final score, all of the individual scores are multiplied by their weight and the results are summed. This results in a decimal score between 0.0 and 1.0 with a higher score indicative of a better match.

### 4.4.8 Set the Ranking Order

The absolute ranking of data base names is based on whether or not the name is an exact phonetic match and on the value of the final score. Exact phonetic matches are always ranked first, followed by similar matches. Within these two categories, names are ranked according to

the final score, with higher scores ranked at the top of the list. It is quite possible that an exact match will receive a lower final score than a similar match (if its spelling and/or culture scores are low, for example), and yet be ranked above the similar match based on its category of "exact match". For example, "KNOX" returns the exact match "NAX" with a lower score (.825) than the similar match "KNAGGS" (.848), but forces all exact matches, including "NAX", to the top of the list.

### 4.4.9 Return a Ranked Set

Finally, the Ranker eliminates names that do not meet or exceed the threshold set in the NS-TDS parameters, unless the name is considered an exact match. Exact phonetic matches are always returned, regardless of their score.

### 4.5 Final Ranking

The purpose of Final Ranking is to incorporate a more accurate phonetic score into the overall ranking. Recall that the phonetic score used by the initial Ranker is calculated by the Filter, using simple regular expressions. This algorithm, while fast, can inflate the phonetic score, producing inaccurate ranking. Further, the Filter calculates using single vowel rules, which can introduce another source of inaccuracy (e.g., "LITZ" = "LUTZ"). Final ranking adjusts the phonetic score by performing a brute force edit distance calculation, using multiple vowel rules. This calculation is performed at this point because it is time-consuming, and must be limited to the smallest possible set of input data to meet performance requirements. Note that Final Ranking is a parameter option, although the default is set to true.

### 4.5.1 Recalculate the Phonetic Score

All names that were retrieved via the similar phonetic search and passed initial ranking are reprocessed to produce an accurate phonetic score. Names that were retrieved via the exact phonetic match search do not need to be recalculated because their phonetic score is always 1.0. First, the names are passed through the appropriate cultural multiple vowel rule set to produce a list of all possible IPA variants. Then, a brute force edit calculation is performed; every variant from the query name is compared to every variant of the data base name by performing a phonetic edit distance calculation. The best score is retained and assigned to the result.

### 4.5.2 Recalculate the Final Score

Using the same logic as that used by the initial Ranker, the Final Score is calculated using the new, more precise phonetic score. This will result in lower scores for some names; if these names fall below the final score threshold, they are removed from the ranked list.

### 4.5.3 Rebuild the Ranked Set

Finally, using the new score, the set of names is ranked again; with exact matches at the top followed by similar matches. Also, the final ranker will only return the maximum number of names requested by the user. The default setting is 145. Thus, it is possible for a name to pass NS-TDS, but not be displayed on output.

### Technical Plan Technology Demonstration System September 10, 1997 (amended)

Contract No. 97-F131000-000

Delivered to the Office of Research and Development

Language Analysis Systems, Inc. 2214 Rock Hill Road—Herndon, VA—20170

### 1.0 Introduction

This Technical Plan describes LAS's proposed design for the Technology Demonstration System (TDS) and includes a conceptual design, the target hardware platform, operating system, support software and development environment, the name data base and a work plan that provides a schedule for development and implementation.

### 2.0 Background

The TDS project is the result of the findings and recommendations of the Name Search Research Project, conducted from September, 1995 through June, 1997. The goal of the Project was to determine the utility and feasibility of using phonological information about pronunciation of person names in order to improve the quality of non-exact automatic name searching. Phase 1 of the Project concluded that there was substantial evidence to support the use of phonological information in automatic name searching. Specifically, the conclusions recommended:

- using the International Phonetic Alphabet (IPA) to represent multiple pronunciations of names unambiguously, and
- measuring articulatory similarity of names through phonetic features and processes.

Phase 2 of the Project built upon the results of Phase 1, specifically by:

- expanding, refining and testing sets of IPA rules from Phase 1 to represent multiple
  pronunciations of Anglo, Arabic, Hispanic and Mandarin Chinese names; test results
  returned at a retrieval rate of 92%;
- exploring a set of factors that contribute to articulatory similarity, including factors at the syllable level.

Phase 2 recommended the development of a Name Search Technology Demonstration System (TDS) to extend and transfer the phonology-based technology from the Name Search Research Project to a functional, automatic, integrated TDS.

### 3.0 Environment

The hardware and software environment are well defined. It is a simple environment that is geared to flexibility and performance. In other words, LAS does not intend to introduce complications by using resource intensive and/or expensive support software or hardware. TDS will be built using the following hardware and software components:

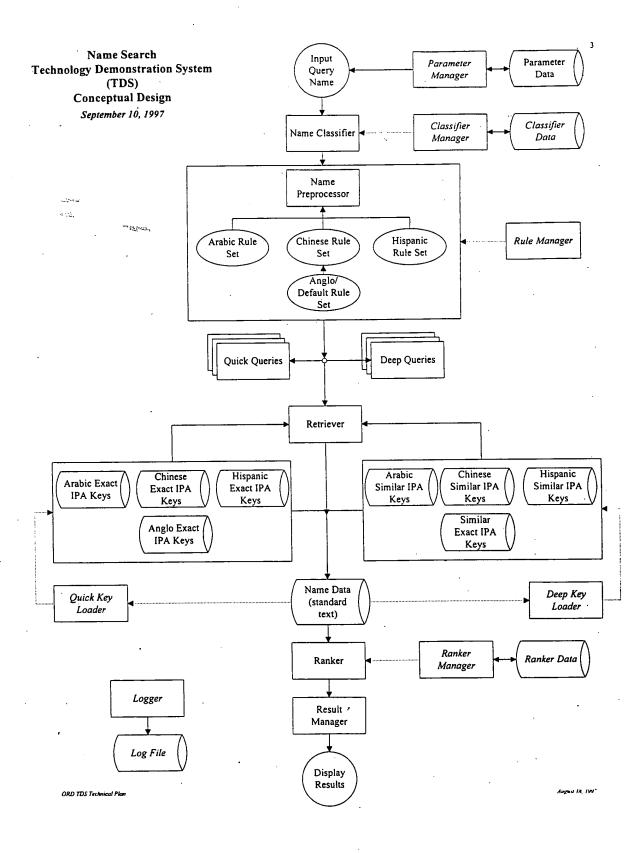

- Standard, high performance Intel-based laptop computers. By purchase time, we expect to configure the machines as follows:
  - Intel Pentium, Pentium Pro or Pentium II CPU;
  - 160 to 512 Mb of memory (160 is the current maximum);
  - 3 Gb of disk storage;
  - High speed CD-ROM (8x minimum);
  - Standard Ethernet network card for high speed data transfer;
  - High resolution monitor with a bright clear screen.
- Windows 32-bit operating environment and development software:
  - Windows 95 or Windows NT 4.x (depending on the processor available);
  - Microsoft Visual C++ version 5.x (for development only);
  - Microsoft Access (support table maintenance);
  - Custom data storage techniques maximizing memory usage (no RDBMS);
  - Multi-threaded architecture to begin displaying responses within 12 seconds.

TDS will run on a top-of-the-line standard laptop computer, a suite of custom developed executables and dynamic link libraries (DLLs) and standard end user software (i.e., MS Access, Excel, etc.). There will be no special or extraordinary system or software requirements.

### 4.0 Conceptual Design

The following diagram gives an overview of the system LAS intends to build. It is based on previous documents developed by the sponsor and LAS and represents research done to date. It identifies the major components and processes to be included in TDS; however, it is a preliminary design, and is subject to change depending on the outcome of further research and time restraints. After the diagram, each of the components and interactions between them is described in further detail.

In the chart, components that are identified in italics are support functions not intended for standard use. They are, however, necessary for LAS to build, tune and test the system.

**Input Query Name** - A simple Graphical User Interface (GUI) will be built to allow the user to enter a name that will be compared to the name data base.

Parameter Manager - LAS will provide options so the user can tune or limit the search. These options will be controlled through the GUI and stored in a Parameter Data set. Parameters currently being considered include:

- exact only (fast) or exact and similar matches;
- level of similarity (loose or tight);
- culture specific matches (Anglo, Arabic, Chinese and/or Hispanic);
- number of returns (maximum/default = 145);
- · bypass name classification.

....

Note that it will not be necessary to set parameters to perform a name search. Default parameters will be used in the event that the user goes directly to the name check screeen.

Name Classifier - The name classifier determines whether the ethnicity of a name is Arabic, Chinese or Hispanic. The LAS name classifier uses a data base of contiguous letter pairs (digraphs) and triplets (trigraphs) that has been statistically analyzed to rank digraphs and trigraphs according to ethnic origin. With this information, it calculates a score for each culture that shows the probability of the name being Arabic, Hispanic and/or Chinese The highest positive score will determine which non-Anglo algorithm to use in addition to the standard Anglo algorithm. Note that it is possible for all scores to be negative, in which case only the Anglo algorithm will be used. This component will be based on an existing system developed in Clipper by LAS that will be converted to C++ to better interface with the other components.

Classifier Manager - This is a simple interface necessary to apply values to the digraphs and trigraphs according to ethnicity. Most likely, LAS will use a standard data base package to manipulate classifier data (i.e., MS Access). Note that the existing classifier data base is already returning adequate results. Improvements will be made if time and resources permit.

Name Preprocessor - At a minimum, this component will convert the input name into one or more IPA representations. Almost certainly, it will generate numerous variants based on different phonetic representations that will be passed to the Retriever. Furthermore, additional information about the query name will be necessary in order to use the similar search keys (i.e., name length, syllabic structure, etc.).

Rule Sets - Four rule sets will be used to convert Roman character representations of names into IPA representations. The default rule set, Anglo, will always be used; the other three, Arabic, Chinese and Hispanic will be used if the name is classified as belonging to one of these ethnic groups and the user has specified that other ethnic variations are to be used. These rule sets will be based on the work done in previous projects. The Anglo rule set will need considerable

modification to support Anglo pronunciations of non-Anglo names. They will be maintained by a Rule Manager, that allows LAS to build and modify rule sets as necessary.

Quick Queries - To ensure that the 12 second initial response time requirement is met, LAS intends to segment and multi-thread searches of the name data base. Quick queries retrieve those records that contain the same IPA characters or the same IPA consonants with a vowel place-holder, or the same IPA consonants. The ultimate retrieval scheme will be determined by further research. This approach will allow TDS to pass a small subset of data to the Ranker and begin returning most of the "best" names quickly. Note that this scheme does not consider differences in name length (i.e., insertion and deletion). The output of the quick query component will be a list of IPA representations that the Retriever will use to extract records for evaluation by the Ranker.

Deep Queries - By far the most difficult problem to solve, deep queries will allow TDS to subset the name data base into phonetically similar sections and account for varying levels of name and possibly syllable length. They must consider the insertion and/or deletion of IPA characters and the proximity of different IPA characters based on the number and importance of features they have in common (e.g., "p" and "b" differ by only one phonetic feature). Almost certainly, deep queries will include all names retrieved by quick queries. If performance is acceptable for deep queries, the quick query logic may become unnecessary. The output of the deep query component will be a list of IPA representations that the Retriever will use to extract records for evaluation by the Ranker.

Retriever - This component accepts query lists from the query preprocessors and passes subsets of the name data base to the Ranker. Operating simultaneously with the query components, it processes query lists in the order that they are received. Each input list will be identified as a "quick" or a "deep" list so that the component can choose the proper key set to use to generate the output list. Once the subset is determined, the retriever will build a list or a range of records to be passed to the Ranker. This list will contain the IPA representation used to retrieve the record, the actual Roman character representation of the name and the rule set used to return the name.

Quick Keys - Each name in the data base will generate one or more IPA representations of the Roman character version. Each rule set can generate different IPA representations. All representations will be stored in the Quick Key data set that will point to the name that generated the particular version. Furthermore, quick keys will be tagged as belonging to the rule set that generated the representation.

Deep Keys - This data set will consist of keys that contain IPA representations, IPA similarity, name length and possibly, syllabic information. It will be designed to allow for subsetting of the name data base into names that are potentially similar to the query name. It must overcome the two major problems in determining name similarity: sounds can be mispronounced (Pine = Bine) and names can be substrings of each other (McDonald = Donald). A key area of research that must be resolved early in the project is the use of indices to represent similar IPA characters (one character to represent "b" and "p").

ORD TDS Technical Plan September 10, 1997

Name Data - This component represents the raw data provided by LAS internally for development and ultimately by the sponsor for the production version of TDS. Each name will be stored in its Roman character representation and will be identified by a record ID. These ID's will be used to tie the raw name to the quick and deep keys.

Key Loaders - Batch programs will be developed that take an ASCII text file of names as input to generate the Name, Quick Key and Deep Key data bases. This program will use the Name Classifier and Name Preprocessor to generate keys and build or rebuild these data bases. It will edit the names and produce a summary statistical report and a detailed error report showing any abnormalities encountered (i.e., invalid length, invalid characters, etc.).

Ranker - This component processes a list of candidate records generated by the Retriever. The list will consist of records containing the IPA key that returned the record, the rule set used to generate the IPA key and the actual name. The Ranker will sort the names in order of match quality based on parameters set in the Ranker Manager data set. Output will be passed dynamically to the Result Manager for real-time display to the user. Ranking methods will be based on schemes developed in phase 2 of the phonology project (regular expression intersection and the "voter scheme"). It will also consider the rule set used to regularize the input name into IPA representations.

Ranker Manager - This is an optional component that will allow LAS and/or the sponsor to rank returns according to different sort schemes. As mentioned above, the ranking schemes will be based on previous work: regular expression intersection or a voter scheme, and possibly, non-phonetic schemes such as: Soundex, digraph analysis, edit distance methods, etc.

Result Manager - This component will accept input from the Ranker, and maintain a deduped, sorted list based on the parameters set by the Ranker Manager. This list will be passed to the GUI for display to the user, and it will be managed dynamically so that the list is constantly being updated as results are processed by the Ranker.

Display Results - This component is the output side of the GUI. It displays the list produced by the Ranker for viewing and other manipulation (printing, saving to a file, etc.) by the user. The outputs are maintained by query name and are updated dynamically as results are returned from the Ranker. In addition to the ranked list of names, the GUI will also display information on why a particular name was chosen and will be given a score that relates to names above and below it on the list.

Logger - This component will be a development and debugger tool for LAS to determine how well TDS is working, and to aid in testing and problem resolution.

5.0 Name Data Base

ORD TDS Technical Plan September 10, 1997

The ultimate target for TDS is a sponsor data base consisting of 3 million unique name segments (i.e., "John" and "Fitzgerald", not "John Fitzgerald"). LAS must generate a similar data base of name segments since the sponsor data base is classified. To do this, LAS will take advantage of numerous resources that will be used without compromising the privacy and sensitivity of the data. That is, only name segments will be extracted from these sources. It will be impossible to tie the TDS names to the source data base. Sources to be used include:

- Visa Lookout Data from the Department of State;
- Passport Lookout Data from the Department of State;
- Census Data from the Department of Commerce;
- Phone Book data from commercial sources;
- Known variant lists.

Should the above sources fail to generate 3 million unique name segments, LAS will resort to generating variations by programmatically manipulating letter variations (i.e., "ck for "ch", "e" for "i", etc.). Currently, LAS has processed 20 million names, which have generated 1 million unique name segments.

Crucial to the successful completion of TDS is an opportunity by LAS to evaluate sponsor data as soon as possible. While not in the Statement of Work or the Project Plan, LAS feels it is advantageous to the sponsor to allow LAS to gain access to the sponsor name data base as soon as possible. While no problems are expected, it is prudent to verify this assumption as the success of TDS is ultimately dependent on the ability to successfully integrate sponsor data.

### 6.0 Work Plan

0.74

Please note that this section of the Technical Plan has been copied in entirety from the Project Plan previously submitted. Attachment A to this plan is a Gantt chart with a Work Breakdown Structure that describes the schedule of development LAS intends to follow. The rest of this section describes the major events in the Gantt chart.

The schedule for the development of TDS spans eight months and consists of four major phases:

- Planning One month to generate project and technical plans.
- Phase 1 Development Three months to resolve research issues, determine a strategy
  to find "similar-to" names, define and validate linguistic search techniques, and
  produce a limited version of TDS for an early look test.
- Phase 2 Development Three months to expand phase 1 into a fully functional
   system to include expanded rule sets that enable TDS to accommodate Anglo
   pronunciations of foreign names and native pronunciations for Arabic, Hispanic and
   Chinese names.

- Implementation Four months (with three months overlapping the development effort) to procure two laptop computers, install the system for the sponsor, provide training, and document the results of the project.
- Maintenance Four months to modify, upgrade and correct TDS at the direction of the sponsor.

Each phase concludes with a specific set of deliverables (both internal to LAS and formal deliveries to the sponsor). There is some flexibility in the schedule, however, the dates set for sponsor deliveries are firm.

### 6.1 Phase 1 Development

The purpose of phase 1 is prove that LAS can develop a viable name search system based on phonetics. The goals are to produce a complete design for TDS and develop a prototype system. Although limited in functionality, the prototype must be complete enough to pass an early look test based on a test plan generated by LAS. The sponsor has the ultimate authority to decide whether or not the prototype justifies further development. Phase 1 consists of the following tasks:

- Research Previous work by LAS has generated many working theories and prototypes/work benches. All of this work must be analyzed further to determine which theories are best applied to TDS. In early September, when this task is scheduled to conclude, LAS will know how all of the major components of TDS will work and will have a conceptual design document that drives further development. In addition, LAS will deliver input specifications for data to be loaded into TDS.
- Development Based on the outcome of the research task, LAS will develop the first limited version of TDS. Ideally prototypes developed during the research task will form the basis for this version of the system. In addition, the Linguistic team will continue to refine their research from the previous period and provide guidance to the Technical
- Test Plan During research and development, a test plan will be developed. First, requirements will be culled from existing documentation and results from the research task. Then, these requirements will be used to develop test scripts. There are four major areas to be tested: functionality, performance, retrieval accuracy and ranking accuracy. The test plan is a deliverable required by the contract.
- Build and Test A week has been reserved in the schedule to integrate the output of the development task, after which there are three'weeks to execute the test, make any corrections and document the results.

While subject to change, the plan calls for the first version of TDS to contain the following features:

- A fully functional name classifier that can identify Arabic, Chinese and Hispanic names.
   The name classifier will be ported to C++ from LAS's already developed PC-NAS system that is currently written in Clipper.
- Name processors for Anglo and Arabic names. Note that in this phase, the Anglo name processor will not include the extended rule set for atypical Anglo names.
- A fully functional name data base with a key structure that accommodates both IPA exact
  match and phonetically "similar to" searching. A program to load raw data into the name
  data base will also be produced during this phase. The name data used will be obtained
  from LAS resources.
- A search engine that when given a query name and it's ethnicity will search the name data base and provide a list of matches.
- A limited version of the ranker with a sorting algorithm to be determined during development.
- A limited graphical user interface (GUI) to allow for evaluation of the TDS.

### 6.2 Phase 2 Development

w. 18

Phase 2 provides three months to complete the development of TDS. Currently, the features to be developed in this phase are:

- Develop the Hispanic and Chinese name processors.
- Extend the Anglo name processor to include rules for atypical Anglo names and pronunciations.
- Complete the Ranker to include a sort algorithm with additional sorts as deemed useful.
- Finalize the GUI to include all features required by the sponsor and/or deemed desirable by LAS.
- Finalize the TDS documentation to include a simple user manual and descriptions of all algorithms.

ORD TDS Technical Plan September 10, 1997

Phase 2 culminates in the execution of an acceptance test with time built in for bug fixes and test documentation.

### 6.3 Implementation

The final task is to deliver the system to the sponsor. LAS will purchase, test and configure two high-end laptop computers, load sponsor data into TDS, provide training, and write a final report.

ORD TDS Technical Plan

September 10, 1997

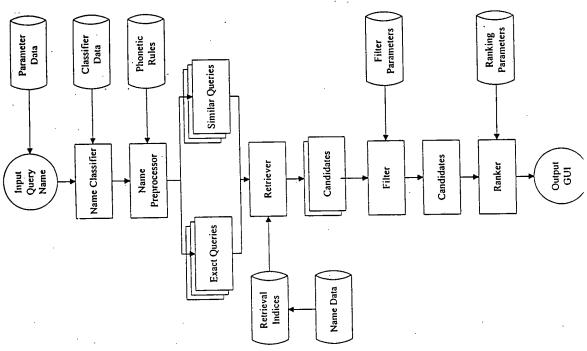

# Technology Demonstration System Acceptance Test Name Search

February 11, 1998

Language Analysis Systems, Inc. 2214 Rock Hill Road—Herndon, VA—20170

# Technology Demonstration System

- · A phonological name search system
- Technology based on the research results of an 18-month project
  - A prototype developed to demonstrate the capabilities of this technology

## Characteristics of TDS

- Each query drives the list of returns
  - no a priori set or group of names
- "on-the-fly", automatic process of associating query name with database names
  - allows multiple relationships among names
- Pronunciation and spelling contribute to measures of similarity
- System returns ranked list of similar names

3

3

Language Analysis Systems, Inc.

TDS Acceptance Test

# Characteristics of TDS (cont.)

- · Culture-based rule sets
- Names are automatically classified as Arabic, Mandarin Chinese, Hispanic or "Other"
  - Arabic, Mandarin Chinese and Hispanic rule sets process names based on automatic classification
    - classification E.g., Arabic rules:  $Qaddaft \sim \underline{Kh}addafy$
- All names are processed by Anglo rules

3

# Key Characteristics of the TDS

- · fast
- principled
- · fully automatic
  - sorted returns
    - multicultural

Language Analysis Systems, Inc.

### Scope of the TDS

- · Not a full retrieval system
- retrieves single names (e.g., Smith)
- · Other factors not covered by TDS:
- Dialect: Chinese Ng = Wu = Huang- Stems and affixes: Vega ~ Delavega
- Typographical errors: JpnesPerceptual issues: Polk misheard as Holtz

# Technical Overview of the TDS

- · Written in Microsoft Visual C++ for Windows NT
  - · Six-month development period
- · Effort concentrated on indexing strategies, search algorithms and ranker
  - · Minimal effort spent on User Interface
- with a 233 MHz Pentium MMX, 160 Mb of • Currently running on an IBM ThinkPad 770 RAM

Language Analysis Systems, Inc.

## TDS Acceptance Test

Purpose of today's Acceptance Test:

To determine whether the TDS satisfies the requirements of the Statement of Work

3

### Requirements of the TDS

- I. The TDS will incorporate a search component using phonetic name search algorithms (IPA exact match and phonetically "similar-to")
- 2. The TDS will incorporate a name classifier component automatically identifying a query name as a member of a specific culture for which culture-specific name processing rules can be applied
  - 3. The cultures to be implemented in the Name Classifier component are Arabic, Chinese, Hispanic and Other (including Anglo)
- 4. The TDS will incorporate a rank-ordering component that ranks the results from the search component, a name database and its supporting database management system, and a graphical user interface

Language Analysis Systems, Inc.

ъ...

- 5. The individual software components that are directly related to name searching should be designed and written to be modular
- 6. The TDS will work on a name database consisting of at least three million names
- 7. The TDS will allow a user to input as a query a name in Romanized form
  - Accepts entry of a single name segment only
- Accepts input length 2 30 characters as valid entry
- Accepts lower and upper case letters as valid entry
- Accepts alphabetic characters and apostrophe as valid entry

match or phonetically similar-to

3

# Requirements of the TDS (cont.)

- 8. Names that have been classified by the Name Classifier as Arabic, Chinese or Hispanic will be processed by their respective language-specific components, as well as by the English (Anglo)-language components. All names will be processed by the Anglo components.
  - 9. The TDS will rank and display retrieved names in order of phonological similarity to the query name, with Exact Matches displayed at the top of an ordered list
- The TDS will include a batch processing component
   The ranking algorithm should be general enough to apply to the full set of names retrieved regardless of whether the technology responsible for the retrieval was IPA exact

Language Analysis Systems, Inc.

₹

- 12. The TDS shall begin to display the results of each query against a name database of about three million names within twelve (12) seconds
  - 13. The user shall be able to select for each query whether "sinilar-to" logic is to be used in the retrieval process
- 14. The user shall be able to select for each query whether the user will bypass the name classifier and manually specify the culture of the query name
- 15. The user shall be able to select for each query whether the name classifier is to be used; if not, the query shall be processed as an English (Anglo) name (in addition to the manually specified culture, if any)

3

19. Each option selected shall become the default option and 18. The TDS display will include the list of hits returned along with each name's six character group number

20. The contractor may include other options that satisfy the needs of its developers and other personnel, as long as the default for those options is off shall apply to all queries until the user changes it

Language Analysis Systems, Inc.

# Requirements of the TDS (cont.)

16. The user shall be able to select for each query the maximum number of hits to be displayed

phonetically "similar-to" technology) shall be displayed 17. The reason a name was retrieved (that is, whether the retrieval of a name was due to IPA exact match or along with the name 3

21. The TDS software shall be written with English comments embedded in the code that implements each algorithm

25. The TDS will accept the following input when performing the pre-processing of the client's names database:
ASCII LEAT file

Requirements of the TDS (cont.)

Allowable characters include ketters of the alphabet and the apostrophe (').

Lower case letters will be converted to upper case Each record will contain two fields separated by a blank as specified below:

Columns I through 6 will contain the Group Number; the first chusacter may be either a 'Z' or a number; the temaining 5 chusacters must contain a digit

Columns 8 through 37 will contain the name. The name must be at least 2 characters long, and no longer than 30 characters

Column 7 must be blank

Client database may exist on 3.5" diskette or CD-ROM

Duplicate names will be rejected

- 22. The comments shall tie blocks of code (a block of code is one or more sequential lines of code) in each algorithm's implementation to the step being implemented in the deliverable English-language narrative that describes the algorithm
  - 23. The TDS should be designed so that new technology can be easily incorporated as it becomes available
    - 24. The TDS will include a batch processing option for results retrieval

3

3

Language Analysis Systems, Inc.

₩....

10

26. Each query name and all the names retrieved by the TDS (not to exceed the limit in use at that time) will be saved in an internal file until the user selects to delete it

27. The TDS will also provide the capability to write the saved data onto a hit file resident on diskette(s) when directed by the user

```

```
{\it H} this is the float version of the above function (yes I know about overloading)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          for (pi = 0; (p_char = arr1(pi)) != BOS; pi++) // BOS is defined as '\0'
